Abstract

Red Hat Developer Toolset is a Red Hat offering for developers on the Red Hat Enterprise Linux platform. The Red Hat Developer Toolset User Guide provides an overview of this product, explains how to invoke and use the Developer Toolset versions of the tools, and links to resources with more in-depth information.

Preface

1. Document Conventions

This manual uses several conventions to highlight certain words and phrases and draw attention to specific pieces of information.

In PDF and paper editions, this manual uses typefaces drawn from the Liberation Fonts set. The Liberation Fonts set is also used in HTML editions if the set is installed on your system. If not, alternative but equivalent typefaces are displayed. Note: Red Hat Enterprise Linux 5 and later include the Liberation Fonts set by default.

1.1. Typographic Conventions

Four typographic conventions are used to call attention to specific words and phrases. These conventions, and the circumstances they apply to, are as follows.

Mono-spaced Bold

Used to highlight system input, including shell commands, file names and paths. Also used to highlight keys and key combinations. For example:

To see the contents of the file my_next_bestselling_novel in your current working directory, enter the cat my_next_bestselling_novel command at the shell prompt and press Enter to execute the command.

The above includes a file name, a shell command and a key, all presented in mono-spaced bold and all distinguishable thanks to context.

Key combinations can be distinguished from an individual key by the plus sign that connects each part of a key combination. For example:

Press Enter to execute the command.

Press Ctrl+Alt+F2 to switch to a virtual terminal.

The first example highlights a particular key to press. The second example highlights a key combination: a set of three keys pressed simultaneously.

If source code is discussed, class names, methods, functions, variable names and returned values mentioned within a paragraph will be presented as above, in mono-spaced bold. For example:

File-related classes include filesystem for file systems, file for files, and dir for directories. Each class has its own associated set of permissions.

Proportional Bold

This denotes words or phrases encountered on a system, including application names; dialog box text; labeled buttons; check-box and radio button labels; menu titles and sub-menu titles. For example:

Choose System → Preferences → Mouse from the main menu bar to launch Mouse Preferences. In the Buttons tab, select the Left-handed mouse check box and click Close to switch the primary mouse button from the left to the right (making the mouse suitable for use in the left hand).

To insert a special character into a gedit file, choose Applications → Accessories →
Character Map from the main menu bar. Next, choose Search → Find… from the Character Map menu bar, type the name of the character in the Search field and click Next. The character you sought will be highlighted in the Character Table. Double-click this highlighted character to place it in the Text to copy field and then click the Copy button. Now switch back to your document and choose Edit → Paste from the gedit menu bar.

The above text includes application names; system-wide menu names and items; application-specific menu names; and buttons and text found within a GUI interface, all presented in proportional bold and all distinguishable by context.

**Mono-spaced Bold Italic or Proportional Bold Italic**

Whether mono-spaced bold or proportional bold, the addition of italics indicates replaceable or variable text. Italics denotes text you do not input literally or displayed text that changes depending on circumstance. For example:

To connect to a remote machine using ssh, type `ssh username@domain.name` at a shell prompt. If the remote machine is `example.com` and your username on that machine is john, type `ssh john@example.com`.

The `mount -o remount file-system` command remounts the named file system. For example, to remount the `/home` file system, the command is `mount -o remount /home`.

To see the version of a currently installed package, use the `rpm -q package` command. It will return a result as follows: `package-version-release`.

Note the words in bold italics above — username, domain.name, file-system, package, version and release. Each word is a placeholder, either for text you enter when issuing a command or for text displayed by the system.

Aside from standard usage for presenting the title of a work, italics denotes the first use of a new and important term. For example:

Publican is a DocBook publishing system.

### 1.2. Pull-quote Conventions

Terminal output and source code listings are set off visually from the surrounding text.

Output sent to a terminal is set in **mono-spaced roman** and presented thus:

```
books        Desktop   documentation  drafts  mss    photos   stuff  svn
books_tests  Desktop1  downloads      images  notes  scripts  svgs
```

Source-code listings are also set in **mono-spaced roman** but add syntax highlighting as follows:
static int kvm_vm_ioctl_deassign_device(struct kvm *kvm,  
    struct kvm_assigned_pci_dev *assigned_dev)
{
    int r = 0;
    struct kvm_assigned_dev_kernel *match;

    mutex_lock(&kvm->lock);
    match = kvm_find_assigned_dev(&kvm->arch.assigned_dev_head,  
        assigned_dev->assigned_dev_id);
    if (!match) {
        printk(KERN_INFO "\%s: device hasn't been assigned before, "  
            "so cannot be deassigned\n", __func__);  
        r = -EINVAL;
        goto out;
    }
    kvm_deassign_device(kvm, match);
    kvm_free_assigned_device(kvm, match);
    out:
    mutex_unlock(&kvm->lock);
    return r;
}

1.3. Notes and Warnings
Finally, we use three visual styles to draw attention to information that might otherwise be overlooked.

**Note**
Notes are tips, shortcuts or alternative approaches to the task at hand. Ignoring a note should have no negative consequences, but you might miss out on a trick that makes your life easier.

**Important**
Important boxes detail things that are easily missed: configuration changes that only apply to the current session, or services that need restarting before an update will apply. Ignoring a box labeled 'Important' will not cause data loss but may cause irritation and frustration.

**Warning**
Warnings should not be ignored. Ignoring warnings will most likely cause data loss.

2. Getting Help and Giving Feedback

2.1. Do You Need Help?
If you experience difficulty with a procedure described in this documentation, visit the Red Hat Customer
Portal at http://access.redhat.com. Through the customer portal, you can:

- search or browse through a knowledgebase of technical support articles about Red Hat products.
- submit a support case to Red Hat Global Support Services (GSS).
- access other product documentation.

Red Hat also hosts a large number of electronic mailing lists for discussion of Red Hat software and technology. You can find a list of publicly available mailing lists at https://www.redhat.com/mailman/listinfo. Click on the name of any mailing list to subscribe to that list or to access the list archives.

2.2. We Need Feedback

If you find a typographical error in this manual, or if you have thought of a way to make this manual better, we would love to hear from you. Please submit a report in Bugzilla: http://bugzilla.redhat.com/ against the product Red Hat Developer Toolset.

When submitting a bug report, be sure to mention the manual's identifier: doc-User_Guide

If you have a suggestion for improving the documentation, try to be as specific as possible when describing it. If you have found an error, please include the section number and some of the surrounding text so we can find it easily.
Part I. Introduction
Chapter 1. Red Hat Developer Toolset

1.1. About Red Hat Developer Toolset

**Red Hat Developer Toolset** is a Red Hat offering for developers on the Red Hat Enterprise Linux platform, and provides a complete set of development and performance analysis tools that can be installed and used on multiple versions of Red Hat Enterprise Linux. Executables built with the Red Hat Developer Toolset toolchain can then also be deployed and run on multiple versions of Red Hat Enterprise Linux. For detailed compatibility information, see Section 1.3, “Compatibility.”

Critically, Red Hat Developer Toolset does not replace the default system tools provided with Red Hat Enterprise Linux 5 or 6 when installed on those platforms. Instead, a parallel set of developer tools provides an alternative, newer version of those tools for optional use by developers. The default compiler and debugger, for example, remain those provided by the base Red Hat Enterprise Linux system.

Table 1.1. Red Hat Developer Toolset Components

<table>
<thead>

<td>3.8.1</td>
<td>An instrumentation framework and a number of tools to profile applications in order to detect memory errors, identify memory management problems, and report any use of improper arguments in system calls.</td>
</tr>
<tr>
<td>OProfile</td>
<td>0.9.8</td>
<td>A system-wide profiler that uses the performance monitoring hardware on the processor to retrieve information about the kernel and executables on the system.</td>
</tr>
<tr>
<td>Dyninst</td>
<td>8.0</td>
<td>A library for instrumenting and working with user-space executables during their execution.</td>
</tr>
</tbody>
</table>

[a] If you intend to develop applications for Red Hat JBoss Middleware or require support for OpenShift Tools, it is recommended that you use Red Hat JBoss Developer Studio.
Red Hat Developer Toolset differs from “Technology Preview” compiler releases previously supplied in Red Hat Enterprise Linux in two important respects:

1. Red Hat Developer Toolset can be used on multiple major and minor releases of Red Hat Enterprise Linux, as detailed in Section 1.3, “Compatibility”.

2. Unlike Technology Preview compilers and other tools shipped in earlier Red Hat Enterprise Linux, Red Hat Developer Toolset is fully supported under Red Hat Enterprise Linux Subscription Level Agreements, is functionally complete, and is intended for production use.

Important bug fixes and security errata are issued to Red Hat Developer Toolset subscribers in a similar manner to Red Hat Enterprise Linux for two years from the release of each major version release. New major versions of Red Hat Developer Toolset is released annually, providing significant updates for existing components and adding major new components. A single minor release, issued six months after each new major version release, provides a smaller update of bug fixes, security errata, and new minor components.

Additionally, the Red Hat Enterprise Linux Application Compatibility Specification also applies to Red Hat Developer Toolset (subject to some constraints on the use of newer C++11 language features, detailed in Section A.2.2.3, “ABI Compatibility”).

### Important

Applications and libraries provided by Red Hat Developer Toolset do not replace the Red Hat Enterprise Linux system versions, nor are they used in preference to the system versions. Using a framework called Software Collections, an additional set of developer tools is installed into the /opt directory and is explicitly enabled by the user on demand using the supplied scl utility.

### 1.2. Main Features

The Red Hat Developer Toolset version of the GNU Compiler Collection (GCC) provides the following features:

- A new register allocator (LRA) has been added, improving code performance.
- A fast memory error detector called AddressSanitizer has been added.
- A fast data race detector called ThreadSanitizer has been added.
- Extremely large functions can now be compiled faster using less memory.
- A new general optimization level has been introduced.
- GCC diagnostic messages now highlight the exact problem source code.
- Various new optimization options have been added.
- DWARF4 is now used as the default debug format.
- GCC now fully implements the C++11 language standard.
- C++11 library support has been extended though is still experimental.
- GCC now supports dynamic initialization of thread-local variables.
- Support has been added for Intel FXSR, XSAVE, and XSAVEOPT instructions.
- New built-in functions added to detect run-time Intel CPU Type and ISA.
- Intel function multi-versioning support added.
- Intel RTM/HLE intrinsics, built-ins, and code generation have been added.
Transactions (the \texttt{-fgnu-tm} option) can now be run using Intel \textbf{TSX} extensions.

Support for AMD family 15h and 16h processors has been added.

Various Fortran changes have been included.

The version of the \textbf{GNU Debugger (GDB)} included in Red Hat Developer Toolset provides the following features:

- Improved and expanded support for Python scripting.
- Improved handling of C++ debuggee executables.
- Improved inferior control commands.
- Improved support for ambiguous line specifications.
- Improved tracepoint support.
- Multi-program debugging.

Additionally, the Red Hat Developer Toolset version of \textbf{binutils} provides these features:

- The new \textbf{gold} linker, which is smaller and faster than \textbf{ld}. Note that \textbf{gold} is not the default linker and must be explicitly enabled by using the \textbf{alternatives} command.
- Support for link-time optimization (LTO) in conjunction with GCC.
- Support for build-IDs, unique numbers to identify executables.
- Support for the \textbf{IFUNC} and \textbf{UNIQUE} symbols that are used by \textbf{glibc} to improve performance. Due to dependencies on a particular version of the \textbf{glibc} library, these symbols are only available on Red Hat Enterprise Linux 6.
- Compressed debug sections for smaller debug info files.

For a full list of changes and features introduced in this release, see Appendix A, \textit{Changes in Version 2.0}.

\section*{1.3. Compatibility}

Red Hat Developer Toolset 2.0 is available for Red Hat Enterprise Linux 5 and 6, both for 32-bit and 64-bit Intel and AMD architectures. \textit{Figure 1.1, “Red Hat Developer Toolset 2.0 Compatibility Matrix”} illustrates the support for binaries built with Red Hat Developer Toolset on a certain version of Red Hat Enterprise Linux when those binaries are run on various other versions of this system.
### 1.4. Getting Access to Red Hat Developer Toolset

Red Hat Developer Toolset is an offering that is distributed as part of the developer subscriptions listed in Table 1.2, “Subscriptions That Provide Red Hat Developer Toolset”. Depending on the subscription management service with which you registered your Red Hat Enterprise Linux system, you can either enable Red Hat Developer Toolset by using the Red Hat Subscription Management, or by using RHN Classic.

For detailed instructions on how to enable Red Hat Developer Toolset using RHN Classic or Red Hat Subscription Management, see the respective section below. For information on how to register your system with one of these subscription management services, see the Red Hat Subscription Management Guide.

#### Important

If you are running a version of Red Hat Enterprise Linux prior to 5.9 or 6.4, you will be unable to download Red Hat Developer Toolset through Red Hat Subscription Management. To obtain Red Hat Developer Toolset, you will need to either update to Red Hat Enterprise Linux 5.9 or 6.4, or register your system with RHN Classic. For more information, see [https://access.redhat.com/site/solutions/129003](https://access.redhat.com/site/solutions/129003).

<td>1-year Unsupported Red Hat Advanced Partner Subscription</td>
</tr>
</tbody>
</table>

1.4.1. Using RHN Classic

If your system is registered with RHN Classic, complete the following steps to subscribe to Red Hat Developer Toolset:

1. Display a list of all channels that are available to you in order to determine the exact name of the Red Hat Developer Toolset channel. To do so, type the following at a shell prompt as root:

```
rhn-channel --available-channels
```

The name of the channel depends on the specific version of Red Hat Enterprise Linux you are using and is in the `rhel-architecture-variant-dts2-version` format, where `architecture` is the system's CPU architecture (`x86_64` or `i386`), `variant` is the Red Hat Enterprise Linux system variant (`server` or `workstation`), and `version` is the Red Hat Enterprise Linux system version (5 or 6).

2. Subscribe the system to the Red Hat Developer Toolset channel by running the following command as root:

```
rhn-channel --add --channel=channel_name
```

Replace `channel_name` with the name you determined in the previous step.

3. To verify the list of channels you are subscribed to, at any time, run as root:

```
rhn-channel --list
```

Once the system is subscribed, you can install Red Hat Developer Toolset as described in Section 1.5, “Installing Red Hat Developer Toolset”. For more information on how to register your system with RHN Classic, see the Red Hat Subscription Management Guide.

1.4.2. Using Red Hat Subscription Management

If your system is registered with Red Hat Subscription Management, complete the following steps to attach a subscription that provides access to the repository for Red Hat Developer Toolset, and then enable that repository:
1. Display a list of all subscriptions that are available for your system to determine the pool ID of a subscription that provides Red Hat Developer Toolset. To do so, type the following at a shell prompt as root:

```
subscription-manager list --available
```

For each available subscription, this command displays its name, unique identifier, expiration date, and other details related to your subscription. The pool ID is listed on a line beginning with Pool Id.

For a complete list of subscriptions that provide access to Red Hat Developer Toolset, see Table 1.2, “Subscriptions That Provide Red Hat Developer Toolset”.

2. Attach the appropriate subscription to your system by running the following command as root:

```
subscription-manager subscribe --pool=pool_id
```

Replace pool_id with the pool ID you determined in the previous step. To verify the list of subscriptions your system has currently attached, at any time, run as root:

```
subscription-manager list --consumed
```

3. Display a list of available Yum repositories to retrieve repository metadata and to determine the exact name of the Red Hat Developer Toolset repositories. As root, type:

```
yum repolist all
```

The repository names depend on the specific version of Red Hat Enterprise Linux you are using, and are in the following format:

```
rhel-variant-dts2-version-rpms
rhel-variant-dts2-version-debug-rpms
rhel-variant-dts2-version-source-rpms
```

Replace variant with the Red Hat Enterprise Linux system variant (server or workstation), and version with the Red Hat Enterprise Linux system version (5 or 6).

4. Enable the appropriate repository. On Red Hat Enterprise Linux 6, you can do so by running the following command as root:

```
yum-config-manager --enable repository
```

On Red Hat Enterprise Linux 5, which does not support the yum-config-manager tool, edit the /etc/yum.repos.d/redhat.repo file, locate the relevant [repository] section, and set the value of the enabled option to 1:

```
enabled = 1
```

Once the subscription is attached to the system, you can install Red Hat Developer Toolset as described in Section 1.5, “Installing Red Hat Developer Toolset”. For more information on how to register your system using Red Hat Subscription Management and associate it with subscriptions, see the Red Hat Subscription Management Guide.

### 1.5. Installing Red Hat Developer Toolset
Red Hat Developer Toolset is distributed as a collection of RPM packages that can be installed, updated, uninstalled, and inspected by using the standard package management tools that are included in Red Hat Enterprise Linux. Note that a valid subscription is required in order to install Red Hat Developer Toolset on your system. For detailed instructions on how to associate your system with an appropriate subscription and get access to the product, see Section 1.4, “Getting Access to Red Hat Developer Toolset”.

### Important

Before installing Red Hat Developer Toolset on a system that is already running the previous version of the product, make sure that the `devtoolset-1.1-gcc-debuginfo` is not installed. To uninstall this package from the system, type the following at a shell prompt as `root`:

```
yum remove devtoolset-1.1-gcc-debuginfo
```

### Important

After installing Red Hat Developer Toolset, it is recommended to apply all available Red Hat Enterprise Linux errata updates to enable all Red Hat Developer Toolset features and apply fixes that may otherwise impact the tools or built code.

### 1.5.1. Installing All Available Components

To install all components that are included in this product, install the `devtoolset-2` package by typing the following at a shell prompt as `root`:

```
yum install devtoolset-2
```

This installs the Eclipse development environment, all development, debugging, and performance monitoring tools, the `scl` utility and other dependent packages to the system. Alternatively, you can choose to install only a selected package group as described in Section 1.5.2, “Installing Individual Package Groups”.

### 1.5.2. Installing Individual Package Groups

To make it easier to install only certain components such as the integrated development environment or the software development toolchain, Red Hat Developer Toolset is distributed with a number of meta packages that allow you to install selected package groups as described in Table 1.3, “Red Hat Developer Toolset Meta Packages”.

#### Table 1.3. Red Hat Developer Toolset Meta Packages

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Description</th>
<th>Installed Components</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>devtoolset-2-ide</code></td>
<td>Integrated Development Environment</td>
<td>Eclipse</td>
</tr>
<tr>
<td><code>devtoolset-2-perftools</code></td>
<td>Performance monitoring tools</td>
<td>SystemTap, Valgrind, OProfile, Dyninst</td>
</tr>
<tr>
<td><code>devtoolset-2-toolchain</code></td>
<td>Development and debugging tools</td>
<td>GCC, GDB, binutils, elfutils, dwz, memstomp, strace</td>
</tr>
</tbody>
</table>
To install any of these meta packages, type the following at a shell prompt as `root`:  

```
yum install package_name...
```

Replace `package_name` with a space-separated list of meta packages you want to install. For example, to install only the Eclipse development environment and packages that depend on it, type as `root`:  

```
~# yum install devtoolset-2-ide
```

Alternatively, you can choose to install all available components as described in Section 1.5.1, "Installing All Available Components".

### 1.5.3. Installing Optional Packages

Red Hat Developer Toolset is distributed with a number of optional packages that are not installed by default. To list all Red Hat Developer Toolset packages that are available to you but not installed on your system, type the following command at a shell prompt:

```
yum list available devtoolset-2-
```

To install any of these optional packages, run as `root`:  

```
yum install package_name...
```

Replace `package_name` with a space-separated list of packages that you want to install. For example, to install the `devtoolset-2-gdb-gdbserver` and `devtoolset-2-gdb-doc` packages, type:

```
~# yum install devtoolset-2-gdb-gdbserver devtoolset-2-gdb-doc
```

**Important**

The `devtoolset-2-gcc-plugin-devel` package depends on the `mpfr-devel` package, which is only available in the `Optional` channel. For detailed instructions on how to subscribe your system to this channel, see the relevant Knowledge article on the Customer Portal.

### 1.5.4. Installing Debugging Information

To install debugging information for any of the Red Hat Developer Toolset packages, make sure that the `yum-utils` package is installed and run the following command as `root`:  

```
depthinfo-install package_name
```

For example, to install debugging information for the `devtoolset-2-dwz` package, type:

```
~# debuginfo-install devtoolset-2-dwz
```

Note that in order to use this command, you need to have access to the repository with these packages. If your system is registered with Red Hat Subscription Management, enable the `rhel-variant-dts2-version-debug-rpms` repository as described in Section 1.4.2, "Using Red Hat Subscription Management". If your system is registered with RHN Classic, subscribe the system to the
rhel-architecture-variant-version-debuginfo channel as described in Section 1.4.1, “Using RHN Classic”. For more information on how to get access to debuginfo packages, see https://access.redhat.com/site/solutions/9907.

1.6. Updating Red Hat Developer Toolset

1.6.1. Updating to a Minor Version
When a new minor version of Red Hat Developer Toolset is available, run the following command as root to update your Red Hat Enterprise Linux installation:

```
yum update
```

This updates all packages on your Red Hat Enterprise Linux system, including the Red Hat Developer Toolset versions the Eclipse development environment, development, debugging, and performance monitoring tools, the scl utility and other dependent packages.

**Important**

Use of Red Hat Developer Toolset requires the removal of any earlier pre-release versions of this product. Additionally, it is not possible to update to Red Hat Developer Toolset 2.0 from a pre-release version of Red Hat Developer Toolset, including beta releases. If you have previously installed any pre-release version of Red Hat Developer Toolset, uninstall it from your system as described in Section 1.7, “Uninstalling Red Hat Developer Toolset” and install the new version as documented in Section 1.5, “Installing Red Hat Developer Toolset”.

1.6.2. Updating to a Major Version
When a new major version of Red Hat Developer Toolset is available, you can install it in parallel with the previous version of the product. For detailed instructions on how to install Red Hat Developer Toolset on your system, see Section 1.5, “Installing Red Hat Developer Toolset”.

1.7. Uninstalling Red Hat Developer Toolset
To uninstall Red Hat Developer Toolset packages from your system, type the following at a shell prompt as root:

```
yum remove devtoolset-2\*
```

This removes the GNU Compiler Collection, GNU Debugger, binutils, and other packages that are part of Red Hat Developer Toolset from the system. To uninstall the scl utility as well, type as root:

```
yum remove scl-utils\*
```

Note that uninstallation of the tools provided by Red Hat Developer Toolset does not affect the Red Hat Enterprise Linux system versions of these tools.

For information on how to uninstall Red Hat Developer Toolset 1.1, see the Red Hat Developer Toolset 1.1 User Guide.
1.8. Additional Resources

For more information about Red Hat Developer Toolset and Red Hat Enterprise Linux, see the resources listed below.

Online Documentation

- **Red Hat Subscription Management Guide** — The *Red Hat Subscription Management Guide* provides detailed information on how to manage subscriptions on Red Hat Enterprise Linux.
- **Red Hat Developer Toolset 2.0 Release Notes** — The *Release Notes for Red Hat Developer Toolset 2.0* contain more information about this product.
- **Red Hat Enterprise Linux 6 Developer Guide** — The *Developer Guide* for Red Hat Enterprise Linux 6 provides more information on the Eclipse IDE, libraries and runtime support, compiling and building, debugging, and profiling on this system.
- **Red Hat Enterprise Linux 5 Installation Guide** — The *Installation Guide* for Red Hat Enterprise Linux 5 explains how to obtain, install, and update the system.
- **Red Hat Enterprise Linux 5 Deployment Guide** — The *Deployment Guide* for Red Hat Enterprise Linux 5 documents relevant information regarding the deployment, configuration, and administration of Red Hat Enterprise Linux 5.

- **Appendix A, Changes in Version 2.0** provides a comprehensive list of changes and improvements over the Red Hat Enterprise Linux system versions of the GNU Compiler Collection, GNU Debugger, and binutils, as well as information about the language, ABI, and debugging compatibility.
Part II. Integrated Development Environments
Chapter 2. Eclipse

Eclipse is a powerful development environment that provides tools for each phase of the development process. It integrates a variety of disparate tools into a unified environment to create a rich development experience, provides a fully configurable user interface, and features a pluggable architecture that allows for extension in a variety of ways. For instance, the Valgrind plug-in allows programmers to perform memory profiling, otherwise performed on the command line, through the Eclipse user interface.

![Figure 2.1. Sample Eclipse Session](image)

Eclipse provides a graphical development environment alternative to traditional interaction with command line tools and as such, it is a welcome alternative to developers who do not want to use the command line interface. The traditional, mostly command line based Linux tools suite (such as *gcc* or *gdb*) and Eclipse offer two distinct approaches to programming.

Red Hat Developer Toolset is distributed with Eclipse 4.3.0, which is based on the Eclipse Foundation's 2013 Eclipse 4.3 “Kepler” simultaneous release. Note that if you intend to develop applications for Red Hat JBoss Middleware or require support for OpenShift Tools, it is recommended that you use Red Hat JBoss Developer Studio.

</tbody>
</table>

[a] This package is installed as a dependency of devtoolset-2-eclipse-linuxtools.

### 2.1. Installing Eclipse

In Red Hat Developer Toolset, the Eclipse development environment is provided as a collection of RPM packages and is automatically installed with the devtoolset-2-ide package as described in Section 1.5, "Installing Red Hat Developer Toolset". For a list of available components, see Table 2.1, "Eclipse Components Included in Red Hat Developer Toolset".
2.1.1. Building Eclipse from the Source RPM Packages

It is recommended that you install the Red Hat Developer Toolset version of Eclipse from the official RPM packages distributed by Red Hat. If, for some reason, you need to build Red Hat Developer Toolset 2.0 Eclipse on Red Hat Enterprise Linux 6 from the supplied source RPM (SRPM) packages, complete the following steps:

1. Install the java-1.7.0-openjdk package from Red Hat Enterprise Linux 6.3 or newer and all its dependencies.
2. Download, build, and install the maven package and all its dependencies from the SRPM packages for Fedora 19.
3. Download, build, and install the tycho package and all its dependencies from the SRPM packages for Fedora 19.
4. Download and build all dependent packages listed in the devtoolset-2-eclipse SRPM package.
5. Download and build the devtoolset-2-eclipse SRPM package.
6. Download and build additional devtoolset-2-eclipse-* SRPM packages.

2.2. Using Eclipse

To start the Red Hat Developer Toolset version of Eclipse, either select Applications → Programming → DTS Eclipse from the panel, or type the following at a shell prompt:

```
scl enable devtoolset-2 'eclipse'
```

During its startup, Eclipse prompts you to select a workspace, that is, a directory in which you want to store your projects. You can either use ~/workspace/, which is the default option, or click the Browse button to browse your file system and select a custom directory. Additionally, you can select the Use this as the default and do not ask again check box to prevent Eclipse from displaying this dialog box the next time you run this development environment. When you are done, click the OK button to confirm the selection and proceed with the startup.

2.2.1. Using the Red Hat Developer Toolset Toolchain

To use the Red Hat Developer Toolset version of Eclipse with support for the GNU Compiler Collection and binutils from Red Hat Developer Toolset, make sure that the devtoolset-2-toolchain package is installed and run the application as described in Section 2.2, “Using Eclipse”. Red Hat Developer Toolset Eclipse uses the Red Hat Developer Toolset toolchain by default.

For detailed instructions on how to install the devtoolset-2-toolchain package in your system, see Section 1.5, “Installing Red Hat Developer Toolset”.

---

**Note**

The Red Hat Developer Toolset version of Eclipse is only available for Red Hat Enterprise Linux 6 on 32-bit and 64-bit Intel and AMD architectures. This version fully supports C, C++, and Java development, but does not provide support for the Fortran programming language.
Important

If you are working on a project that you previously built with the Red Hat Enterprise Linux version of the GNU Compiler Collection, make sure that you discard all previous build results. To do so, open the project in Eclipse and select **Project → Clean** from the menu.

### 2.2.2. Using the Red Hat Enterprise Linux Toolchain

To use the Red Hat Developer Toolset version of Eclipse with support for the toolchain distributed with Red Hat Enterprise Linux, either uninstall `devtoolset-2-gcc`, `devtoolset-2-binutils`, and related packages from your system, or change the configuration of the project to use absolute paths to the Red Hat Enterprise Linux system versions of `gcc`, `g++`, and `as`.

To uninstall the Red Hat Developer Toolset toolchain from the system, type the following at a shell prompt as **root**:

```
yum remove devtoolset-2-gcc* devtoolset-2-binutils*
```

To configure Eclipse to explicitly use the Red Hat Enterprise Linux system versions of the tools for the current project, complete the following steps:

1. In the C/C++ perspective, choose **Project → Properties** from the main menu bar to open the project properties.
2. In the menu on the left-hand side of the dialog box, click **C/C++ Build → Settings**.
3. Select the **Tool Settings** tab.
4. If you are working on a C project:
   a. select **GCC C Compiler** or **Cross GCC Compiler** and change the value of the **Command** field to:
      ```
      /usr/bin/gcc
      ```
   b. select **GCC C Linker** or **Cross GCC Linker** and change the value of the **Command** field to:
      ```
      /usr/bin/gcc
      ```
   c. select **GCC Assembler** or **Cross GCC Assembler** and change the value of the **Command** field to:
      ```
      /usr/bin/as
      ```

   If you are working on a C++ project:
   a. select **GCC C++ Compiler** or **Cross G++ Compiler** and change the value of the **Command** field to:
      ```
      /usr/bin/g++
      ```
   b. select **GCC C Compiler** or **Cross GCC Compiler** and change the value of the **Command** field to:
c. select **GCC C++ Linker** or **Cross G++ Linker** and change the value of the **Command** field to:

```
/usr/bin/g++
```

d. select **GCC Assembler** or **Cross GCC Assembler** and change the value of the **Command** field to:

```
/usr/bin/as
```

5. Click the **OK** button to save the configuration changes.

### 2.3. Additional Resources

A detailed description of Eclipse and all its features is beyond the scope of this book. For more information, see the resources listed below.

**Installed Documentation**

- Eclipse includes a built-in **Help** system which provides extensive documentation for each integrated feature and tool. This greatly decreases the initial time investment required for new developers to become fluent in its use. The use of this Help section is detailed in the *Red Hat Enterprise Linux Developer Guide* linked below.

**Online Documentation**

- [Red Hat Enterprise Linux 6 Developer Guide](#) — The *Developer Guide* for Red Hat Enterprise Linux 6 provides more information on Eclipse, including a description of the user interface, overview of available development toolkits, or instructions on how to use it to build RPM packages.

**See Also**

- [Section A.1, "Changes in Eclipse"](#) provides a comprehensive list of features and improvements over the Red Hat Enterprise Linux system version of the Eclipse development environment.
- [Chapter 1, Red Hat Developer Toolset](#) provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- [Chapter 3, GNU Compiler Collection (GCC)](#) provides information on how to compile programs written in C, C++, and Fortran on the command line.
Part III. Development Tools
Chapter 3. GNU Compiler Collection (GCC)

The GNU Compiler Collection, commonly abbreviated GCC, is a portable compiler suite with support for a wide selection of programming languages.

Red Hat Developer Toolset is distributed with GCC 4.8. This version is more recent than the version included in Red Hat Enterprise Linux and provides numerous bug fixes and enhancements, including optimization for various new Intel and AMD processors, support for OpenMP 3.1 and link-time optimization. This version also includes experimental support for the C++11 standard, C++11 atomic types, and Transactional Memory. For a detailed list of changes, see Section A.2, “Changes in GCC”.

3.1. GNU C Compiler

3.1.1. Installing the C Compiler

In Red Hat Developer Toolset, the GNU C compiler is provided by the devtoolset-2-gcc package and is automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

3.1.2. Using the C Compiler

To compile a C program on the command line, run the gcc compiler as follows:

```
scl enable devtoolset-2 'gcc -o output_file source_file...'
```

This creates a binary file named output_file in the current working directory. If the -o option is omitted, the compiler creates a file named a.out by default.

When you are working on a project that consists of several source files, it is common to compile an object file for each of the source files first and then link these object files together. This way, when you change a single source file, you can recompile only this file without having to compile the entire project. To compile an object file on the command line, run the following command:

```
scl enable devtoolset-2 'gcc -o object_file -c source_file'
```

This creates an object file named object_file. If the -o option is omitted, the compiler creates a file named after the source file with the .o file extension. To link object files together and create a binary file, run:

```
scl enable devtoolset-2 'gcc -o output_file object_file...'
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset gcc as default:

```
scl enable devtoolset-2 'bash'
```
Note

To verify the version of gcc you are using at any point, type the following at a shell prompt:

```
which gcc
```

Red Hat Developer Toolset's gcc executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset gcc:

```
gcc -v
```

Important

Some newer library features are statically linked into applications built with Red Hat Developer Toolset to support execution on multiple versions of Red Hat Enterprise Linux. This adds a small additional security risk as normal Red Hat Enterprise Linux errata would not change this code. If the need for developers to rebuild their applications due to such an issue arises, Red Hat will signal this via a security erratum. Developers are strongly advised not to statically link their entire application for the same reasons.

Example 3.1. Compiling a C Program on the Command Line

Consider a source file named hello.c with the following contents:

```c
#include <stdio.h>

int main(int argc, char *argv[]) {
    printf("Hello, World!\n");
    return 0;
}
```

To compile this source code on the command line by using the gcc compiler from Red Hat Developer Toolset, type:

```
~]$ scl enable devtoolset-2 'gcc -o hello hello.c'
```

This creates a new binary file called hello in the current working directory.

3.1.3. Running a C Program

When gcc compiles a program, it creates an executable binary file. To run this program on the command line, change to the directory with the executable file and type:

```
./file_name
```
Example 3.2. Running a C Program on the Command Line

Assuming that you have successfully compiled the **hello** binary file as shown in Example 3.1, “Compiling a C Program on the Command Line”, you can run it by typing the following at a shell prompt:

```
~]$ ./hello
Hello, World!
```

3.2. GNU C++ Compiler

3.2.1. Installing the C++ Compiler

In Red Hat Developer Toolset, the GNU C++ compiler is provided by the *devtoolset-2-gcc-c++* package and is automatically installed with the *devtoolset-2-toolchain* package as described in Section 1.5, “Installing Red Hat Developer Toolset”.

3.2.2. Using the C++ Compiler

To compile a C++ program on the command line, run the **g++** compiler as follows:

```
scl enable devtoolset-2 'g++ -o output_file source_file...'
```

This creates a binary file named *output_file* in the current working directory. If the **-o** option is omitted, the **g++** compiler creates a file named *a.out* by default.

When you are working on a project that consists of several source files, it is common to compile an object file for each of the source files first and then link these object files together. This way, when you change a single source file, you can recompile only this file without having to compile the entire project.

To compile an object file on the command line, run the following command:

```
scl enable devtoolset-2 'g++ -o object_file -c source_file'
```

This creates an object file named *object_file*. If the **-o** option is omitted, the **g++** compiler creates a file named after the source file with the **.o** file extension. To link object files together and create a binary file, run:

```
scl enable devtoolset-2 'g++ -o output_file object_file...'
```

Note that you can execute any command using the **scl** utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset **g++** as default:

```
scl enable devtoolset-2 'bash'
```
Note

To verify the version of \texttt{g++} you are using at any point, type the following at a shell prompt:

\begin{verbatim}
which g++
\end{verbatim}

Red Hat Developer Toolset's \texttt{g++} executable path will begin with \texttt{/opt}. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset \texttt{g++}:

\begin{verbatim}
g++ -v
\end{verbatim}

Important

Some newer library features are statically linked into applications built with Red Hat Developer Toolset to support execution on multiple versions of Red Hat Enterprise Linux. This adds a small additional security risk as normal Red Hat Enterprise Linux errata would not change this code. If the need for developers to rebuild their applications due to such an issue arises, Red Hat will signal this via a security erratum. Developers are strongly advised not to statically link their entire application for the same reasons.

Example 3.3. Compiling a C++ Program on the Command Line

Consider a source file named \texttt{hello.cpp} with the following contents:

\begin{verbatim}
#include <iostream>

using namespace std;

int main(int argc, char *argv[]) {
    cout << "Hello, World!" << endl;
    return 0;
}
\end{verbatim}

To compile this source code on the command line by using the \texttt{g++} compiler from Red Hat Developer Toolset, type:

\begin{verbatim}
~]$ scl enable devtoolset-2 'g++ -o hello hello.cpp'
\end{verbatim}

This creates a new binary file called \texttt{hello} in the current working directory.

3.2.3. Running a C++ Program

When \texttt{g++} compiles a program, it creates an executable binary file. To run this program on the command line, change to the directory with the executable file and type:

\begin{verbatim}
./file_name
\end{verbatim}
Example 3.4. Running a C++ Program on the Command Line

Assuming that you have successfully compiled the hello binary file as shown in Example 3.3, “Compiling a C++ Program on the Command Line”, you can run it by typing the following at a shell prompt:

```
~$ ./hello
Hello, World!
```

3.3. GNU Fortran Compiler

3.3.1. Installing the Fortran Compiler

In Red Hat Developer Toolset, the GNU Fortran compiler is provided by the devtoolset-2-gcc-gfortran package and is automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

3.3.2. Using the Fortran Compiler

To compile a Fortran program on the command line, run the gfortran compiler as follows:

```
scl enable devtoolset-2 'gfortran -o output_file source_file...
```

This creates a binary file named output_file in the current working directory. If the -o option is omitted, the compiler creates a file named a.out by default.

When you are working on a project that consists of several source files, it is common to compile an object file for each of the source files first and then link these object files together. This way, when you change a single source file, you can recompile only this file without having to compile the entire project. To compile an object file on the command line, run the following command:

```
scl enable devtoolset-2 'gfortran -o object_file -c source_file'
```

This creates an object file named object_file. If the -o option is omitted, the compiler creates a file named after the source file with the .o file extension. To link object files together and create a binary file, run:

```
scl enable devtoolset-2 'gfortran -o output_file object_file...
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset gfortran as default:

```
scl enable devtoolset-2 'bash'
```
Note

To verify the version of gfortran you are using at any point, type the following at a shell prompt:

```
which gfortran
```

Red Hat Developer Toolset's gfortran executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset gfortran:

```
gfortran -v
```

Important

Some newer library features are statically linked into applications built with Red Hat Developer Toolset to support execution on multiple versions of Red Hat Enterprise Linux. This adds a small additional security risk as normal Red Hat Enterprise Linux errata would not change this code. If the need for developers to rebuild their applications due to such an issue arises, Red Hat will signal this via a security erratum. Developers are strongly advised not to statically link their entire application for the same reasons.

Example 3.5. Compiling a Fortran Program on the Command Line

Consider a source file named `hello.f` with the following contents:

```
program hello
  print *, "Hello, World!"
end program hello
```

To compile this source code on the command line by using the gfortran compiler from Red Hat Developer Toolset, type:

```
~]$ scl enable devtoolset-2 'gfortran -o hello hello.f'
```

This creates a new binary file called `hello` in the current working directory.

3.3.3. Running a Fortran Program

When gfortran compiles a program, it creates an executable binary file. To run this program on the command line, change to the directory with the executable file and type:

```
./file_name
```
Example 3.6. Running a Fortran Program on the Command Line

Assuming that you have successfully compiled the **hello** binary file as shown in Example 3.5, “Compiling a Fortran Program on the Command Line”, you can run it by typing the following at a shell prompt:

```bash
~]$ ./hello
Hello, World!
```

3.4. Additional Resources

A detailed description of the GNU Compiler Collections and its features is beyond the scope of this book. For more information, see the resources listed below.

**Installed Documentation**

- **gcc(1)** — The manual page for the **gcc** compiler provides detailed information on its usage; with few exceptions, **g++** accepts the same command line options as **gcc**. To display the manual page for the version included in Red Hat Developer Toolset, type:

  ```bash
  scl enable devtoolset-2 'man gcc'
  ```

- **gfortran(1)** — The manual page for the **gfortran** compiler provides detailed information on its usage. To display the manual page for the version included in Red Hat Developer Toolset, type:

  ```bash
  scl enable devtoolset-2 'man gfortran'
  ```

- **C++ Standard Library Documentation** — Documentation on the C++ standard library can be optionally installed by typing the following at a shell prompt as **root**:

  ```bash
  yum install devtoolset-2-libstdc++-docs
  ```

**Online Documentation**

- [Red Hat Enterprise Linux 6 Developer Guide](#) — The Developer Guide for Red Hat Enterprise Linux 6 provides in-depth information about GCC.
- [Using the GNU Compiler Collection](#) — The official GCC manual provides an in-depth description of the GNU compilers and their usage.
- [The GNU C++ Library](#) — The GNU C++ library documentation provides detailed information about the GNU implementation of the standard C++ library.
- [The GNU Fortran Compiler](#) — The GNU Fortran compiler documentation provides detailed information on **gfortran**'s usage.

**See Also**

- Section A.2, “Changes in GCC” provides a comprehensive list of features and improvements over the Red Hat Enterprise Linux system version of the GNU Compiler Collection and the version distributed...
in the previous release of Red Hat Developer Toolset, as well as information about the language, ABI, and debugging compatibility.

- **Chapter 1, Red Hat Developer Toolset** provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- **Chapter 2, Eclipse** provides a general introduction to the Eclipse development environment, and describes how to use it with the tools from Red Hat Developer Toolset.
- **Chapter 4, binutils** explains how to use the binutils, a collection of binary tools to inspect and manipulate object files and binaries.
- **Chapter 5, elfutils** explains how to use elfutils, a collection of binary tools to inspect and manipulate ELF files.
- **Chapter 6, dwz** explains how to use dwz to optimize DWARF debugging information contained in ELF shared libraries and ELF executables for size.
- **Chapter 7, GNU Debugger (GDB)** provides information on how to debug programs written in C, C++, and Fortran.
Chapter 4. binutils

binutils is a collection of various binary tools such as the GNU linker, GNU assembler, and other utilities that allow you to inspect and manipulate object files and binaries. See Table 4.1, “Tools Included in binutils for Red Hat Developer Toolset” for a complete list of binary tools that are distributed with the Red Hat Developer Toolset version of binutils.

Red Hat Developer Toolset is distributed with binutils 2.23.52. This version is more recent than the version included in Red Hat Enterprise Linux and provides numerous bug fixes and enhancements, including the new gold linker, several new command line options, improvements to the linker script language, and support for link-time optimization, compressed debug sections, and new instruction sets. For a detailed list of changes, see Section A.3, “Changes in binutils”.

</table>

4.1. Installing binutils

In Red Hat Developer Toolset, binutils are provided by the devtoolset-2-binutils package and are automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

4.2. Using the GNU Assembler

To produce an object file from an assembly language program, run the as tool as follows:
This creates an object file named `object_file` in the current working directory.

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `as` as default:

```bash
scl enable devtoolset-2 'bash'
```

**Note**

To verify the version of `as` you are using at any point, type the following at a shell prompt:

```
which as
```

Red Hat Developer Toolset's `as` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `as`:

```
as -v
```

### 4.3. Using the GNU Linker

To create an executable binary file or a library from object files, run the `ld` tool as follows:

```bash
scl enable devtoolset-2 'ld [option...] -o output_file object_file...'
```

This creates a binary file named `output_file` in the current working directory. If the `-o` option is omitted, the compiler creates a file named `a.out` by default.

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `ld` as default:

```bash
scl enable devtoolset-2 'bash'
```
4.4. Using Other Binary Tools

The binutils provide many binary tools other than a linker and assembler. For a complete list of these tools, see Table 4.1, “Tools Included in binutils for Red Hat Developer Toolset”.

To execute any of the tools that are part of binutils, run the command as follows:

```
scl enable devtoolset-2 'tool [option...] file_name'
```

See Table 4.1, “Tools Included in binutils for Red Hat Developer Toolset” for a list of tools that are distributed with binutils. For example, to use the `objdump` tool to inspect an object file, type:

```
scl enable devtoolset-2 'objdump [option...] object_file'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset binary tools as default:

```
scl enable devtoolset-2 'bash'
```

4.5. Additional Resources
A detailed description of binutils is beyond the scope of this book. For more information, see the resources listed below.

**Installed Documentation**

- `as(1)`, `ld(1)`, `addr2line(1)`, `ar(1)`, `c++filt(1)`, `dwp(1)`, `elfedit(1)`, `gprof(1)`, `nm(1)`, `objcopy(1)`, `objdump(1)`, `ranlib(1)`, `readelf(1)`, `size(1)`, `strings(1)`, `strip(1)` — Manual pages for various binutils tools provide more information about their respective usage. To display a manual page for the version included in Red Hat Developer Toolset, type:

  ```bash
  scl enable devtoolset-2 'man tool'
  ```

**Online Documentation**

- [Documentation for binutils](#) — The binutils documentation provides an in-depth description of the binary tools and their usage.

**See Also**

- [Section A.3, “Changes in binutils”](#) provides a comprehensive list of features and improvements over the Red Hat Enterprise Linux system version of binutils and the version distributed in the previous release of Red Hat Developer Toolset.
- [Chapter 1, Red Hat Developer Toolset](#) provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- [Chapter 5, elfutils](#) explains how to use elfutils, a collection of binary tools to inspect and manipulate ELF files.
- [Chapter 3, GNU Compiler Collection (GCC)](#) provides information on how to compile programs written in C, C++, and Fortran.
Chapter 5. elfutils

elfutils is a collection of various binary tools such as eu-objdump, eu-readelf, and other utilities that allow you to inspect and manipulate ELF files. See Table 5.1, "Tools Included in elfutils for Red Hat Developer Toolset" for a complete list of binary tools that are distributed with the Red Hat Developer Toolset version of elfutils.

Red Hat Developer Toolset is distributed with elfutils 0.155. This version is more recent than the version included in Red Hat Enterprise Linux and provides numerous bug fixes and enhancements.

Table 5.1. Tools Included in elfutils for Red Hat Developer Toolset

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eu-add2line</td>
<td>Translates addresses into file names and line numbers.</td>
</tr>
<tr>
<td>eu-ar</td>
<td>Creates, modifies, and extracts files from archives.</td>
</tr>
<tr>
<td>eu-elfcmp</td>
<td>Compares relevant parts of two ELF files for equality.</td>
</tr>
<tr>
<td>eu-elflint</td>
<td>Verifies that ELF files are compliant with the generic ABI (gABI) and processor-specific supplement ABI (psABI) specification.</td>
</tr>
<tr>
<td>eu-findtextrel</td>
<td>Locates the source of text relocations in files.</td>
</tr>
<tr>
<td>eu-make-debug-archive</td>
<td>Creates an offline archive for debugging.</td>
</tr>
<tr>
<td>eu-nm</td>
<td>Lists symbols from object files.</td>
</tr>
<tr>
<td>eu-objdump</td>
<td>Displays information from object files.</td>
</tr>
<tr>
<td>eu-ranlib</td>
<td>Generates an index to the contents of an archive to make access to this archive faster.</td>

<td>Displays printable character sequences in files.</td>
</tr>
<tr>
<td>eu-strip</td>
<td>Discards all symbols from object files.</td>
</tr>
<tr>
<td>eu-unstrip</td>
<td>Combines stripped files with separate symbols and debug information.</td>
</tr>
</tbody>
</table>

5.1. Installing elfutils

In Red Hat Developer Toolset, elfutils is provided by the devtoolset-2-elfutils package and is automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

5.2. Using elfutils

To execute any of the tools that are part of elfutils, run the command as follows:

```
scl enable devtoolset-2 'tool [option...] file_name'
```

See Table 5.1, “Tools Included in elfutils for Red Hat Developer Toolset” for a list of tools that are distributed with elfutils. For example, to use the eu-objdump tool to inspect an object file, type:

```
scl enable devtoolset-2 'eu-objdump [option...] object_file'
```
Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset binary tools as default:

```
scl enable devtoolset-2 'bash'
```

**Note**

To verify the version of elfutils you are using at any point, type the following at a shell prompt:

```
which eu-objdump
```

Red Hat Developer Toolset's `eu-objdump` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `eu-objdump`:

```
eu-objdump -V
```

### 5.3. Additional Resources

A detailed description of elfutils is beyond the scope of this book. For more information, see the resources listed below.

**See Also**

- [Section A.4, “Changes in elfutils”](#) provides a comprehensive list of features and improvements over the Red Hat Enterprise Linux system version of elfutils and the version distributed in the previous release of Red Hat Developer Toolset.
- [Chapter 1, Red Hat Developer Toolset](#) provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- [Chapter 3, GNU Compiler Collection (GCC)](#) provides information on how to compile programs written in C, C++, and Fortran.
- [Chapter 4, binutils](#) explains how to use the binutils, a collection of binary tools to inspect and manipulate object files and binaries.
- [Chapter 6, dwz](#) explains how to use dwz to optimize DWARF debugging information contained in ELF shared libraries and ELF executables for size.
Chapter 6. dwz

dwz is a command line tool that attempts to optimize DWARF debugging information contained in ELF shared libraries and ELF executables for size. To do so, dwz replaces DWARF information representation with equivalent smaller representation where possible, and reduces the amount of duplication by using techniques from Appendix E of the DWARF Standard.

Red Hat Developer Toolset is distributed with dwz 0.11.

6.1. Installing dwz

In Red Hat Developer Toolset, the dwz utility is provided by the devtoolset-2-dwz package and is automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

6.2. Using dwz

To optimize DWARF debugging information in a binary file, run the dwz tool as follows:

```
scl enable devtoolset-2 'dwz [option...] file_name'
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset dwz as default:

```
scl enable devtoolset-2 'bash'
```

Note

To verify the version of dwz you are using at any point, type the following at a shell prompt:

```
which dwz
```

Red Hat Developer Toolset's dwz executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset dwz:

```
dwz -v
```

6.3. Additional Resources

A detailed description of dwz and its features is beyond the scope of this book. For more information, see the resources listed below.

Installed Documentation

- dwz(1) — The manual page for the dwz utility provides detailed information on its usage. To display the manual page for the version included in Red Hat Developer Toolset, type:
scl enable devtoolset-2 'man dwz'

See Also

- [Section A.5, “Changes in dwz”](#) provides a comprehensive list of features and enhancements over the version of dwz distributed in the previous release of Red Hat Developer Toolset.
- [Chapter 1, Red Hat Developer Toolset](#) provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- [Chapter 3, GNU Compiler Collection (GCC)](#) provides information on how to compile programs written in C, C++, and Fortran.
- [Chapter 4, binutils](#) explains how to use the binutils, a collection of binary tools to inspect and manipulate object files and binaries.
- [Chapter 5, elfutils](#) explains how to use elfutils, a collection of binary tools to inspect and manipulate ELF files.
Part IV. Debugging Tools
Chapter 7. GNU Debugger (GDB)

The GNU Debugger, commonly abbreviated as GDB, is a command line tool that can be used to debug programs written in various programming languages. It allows you to inspect memory within the code being debugged, control the execution state of the code, detect the execution of particular sections of code, and much more.

Red Hat Developer Toolset is distributed with GDB 7.6. This version is more recent than the version included in Red Hat Enterprise Linux and provides numerous bug fixes and enhancements, including improved support for Python scripting, ambiguous line specifications, and tracepoints, as well as improved inferior control commands and handling of C++ debugee executables. For a detailed list of changes, see Section A.6, “Changes in GDB”.

7.1. Installing the GNU Debugger

In Red Hat Developer Toolset, the GNU Debugger is provided by the devtoolset-2-gdb package and is automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

7.2. Preparing a Program for Debugging

Compiling Programs with Debugging Information

To compile a C program with debugging information that can be read by the GNU Debugger, make sure the gcc compiler is run with the -g option. To do so on the command line, use a command in the following form:

```
scl enable devtoolset-2 'gcc -g -o output_file input_file...'
```

Similarly, to compile a C++ program with debugging information, run:

```
scl enable devtoolset-2 'g++ -g -o output_file input_file...'
```
Example 7.1. Compiling a C Program With Debugging Information

Consider a source file named fibonacci.c that has the following contents:

```c
#include <stdio.h>
#include <limits.h>

int main (int argc, char *argv[]) {
    unsigned long int a = 0;
    unsigned long int b = 1;
    unsigned long int sum;

    while (b < LONG_MAX) {
        printf("%ld ", b);
        sum = a + b;
        a = b;
        b = sum;
    }
    return 0;
}
```

To compile this program on the command line using GCC from Red Hat Developer Toolset with debugging information for the GNU Debugger, type:

```
[~]$ scl enable devtoolset-2 'gcc -g -o fibonacci fibonacci.c'
```

This creates a new binary file called fibonacci in the current working directory.

Installing Debugging Information for Existing Packages

To install debugging information for a package that is already installed on the system, type the following at a shell prompt as root:

```
debuginfo-install package_name
```

Note that the yum-utils package must be installed for the debuginfo-install utility to be available on your system.

Example 7.2. Installing Debugging Information for the glibc Package

To install debugging information for the glibc package, type:

```
[~]# debuginfo-install glibc
Loaded plugins: product-id, refresh-packagekit, subscription-manager
--> Running transaction check
----> Package glibc-debuginfo.x86_64 0:2.12-1.47.el6_2.5 will be installed
...
```

7.3. Running the GNU Debugger
To run the GNU Debugger on a program you want to debug, type the following at a shell prompt:

```
scl enable devtoolset-2 'gdb file_name'
```

This starts the `gdb` debugger in interactive mode and displays the default prompt, `(gdb)`. To quit the debugging session and return to the shell prompt, run the following command at any time:

```
quit
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `gdb` as default:

```
scl enable devtoolset-2 'bash'
```

To verify the version of `gdb` you are using at any point, type the following at a shell prompt:

```
which gdb
```

Red Hat Developer Toolset's `gdb` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `gdb`:

```
gdb -v
```

### Example 7.3. Running the gdb Utility on the fibonacci Binary File

Assuming that you have successfully compiled the `fibonacci` binary file as shown in Example 7.1, “Compiling a C Program With Debugging Information”, you can start debugging it with `gdb` by typing the following at a shell prompt:

```
~]$ scl enable devtoolset-2 'gdb fibonacci'
GNU gdb (GDB) Red Hat Enterprise Linux (7.4.50.20120120-43.el6)
Copyright (C) 2012 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law. Type "show copying"
and "show warranty" for details.
This GDB was configured as "x86_64-redhat-linux-gnu".
For bug reporting instructions, please see:
(gdb)
```

### 7.4. Listing Source Code

To view the source code of the program you are debugging, run the following command:
Before you start the execution of the program you are debugging, \texttt{gdb} displays first ten lines of the source code and any subsequent use of this command lists another ten lines. Once you start the execution, \texttt{gdb} displays the lines that are surrounding the line on which the execution stops, typically when you set a breakpoint.

You can also display the code that is surrounding a particular line. To do so, run the command in the following form:

\begin{verbatim}
list [file_name:]line_number
\end{verbatim}

Similarly, to display the code that is surrounding the beginning of a particular function, run:

\begin{verbatim}
list [file_name:]function_name
\end{verbatim}

Note that you can change the number of lines the \texttt{list} command displays by running the following command:

\begin{verbatim}
set listsize number
\end{verbatim}

\textbf{Example 7.4. Listing the Source Code of the fibonacci Binary File}

The \texttt{fibonacci.c} file listed in \textit{Example 7.1, “Compiling a C Program With Debugging Information”} has exactly 17 lines. Assuming that you have compiled it with debugging information and you want the \texttt{gdb} utility to be capable of listing the entire source code, you can run the following command to change the number of listed lines to 20:

\begin{verbatim}
(gdb) set listsize 20
\end{verbatim}

You can now display the entire source code of the file you are debugging by running the \texttt{list} command with no additional arguments:

\begin{verbatim}
(gdb) list
1       #include <stdio.h>  
2       #include <limits.h>  
3       int main (int argc, char *argv[]) {  
4           unsigned long int a = 0;  
5           unsigned long int b = 1;  
6           unsigned long int sum;  
7       8           while (b < LONG_MAX) {  
9               printf("%ld ", b);  
10               sum = a + b;  
11               a = b;  
12               b = sum;  
13           }  
14       15           return 0;  
16       17       }
\end{verbatim}
7.5. Setting Breakpoints

Setting a New Breakpoint
To set a new breakpoint at a certain line, run the following command:

```
break [file_name:]line_number
```

You can also set a breakpoint on a certain function:

```
break [file_name:]function_name
```

Example 7.5. Setting a New Breakpoint
Assuming that you have compiled the `fibonacci.c` file listed in Example 7.1, "Compiling a C Program With Debugging Information" with debugging information, you can set a new breakpoint at line 10 by running the following command:

```
(gdb) break 10
Breakpoint 1 at 0x4004e5: file fibonacci.c, line 10.
```

Listing Breakpoints
To display a list of currently set breakpoints, run the following command:

```
info breakpoints
```

Example 7.6. Listing Breakpoints
Assuming that you have followed the instructions in Example 7.5, "Setting a New Breakpoint", you can display the list of currently set breakpoints by running the following command:

```
(gdb) info breakpoints
Num Type             Disp Enb Address            What
   1 breakpoint keep y 0x000000000004004e5 in main at fibonacci.c:10
```

Deleting Existing Breakpoints
To delete a breakpoint that is set at a certain line, run the following command:

```
clear line_number
```

Similarly, to delete a breakpoint that is set on a certain function, run:

```
clear function_name
```

You can also delete all breakpoints at once. To do so, run the `clear` command with no additional arguments:
Example 7.7. Deleting an Existing Breakpoint

Assuming that you have compiled the `fibonacci.c` file listed in Example 7.1, “Compiling a C Program With Debugging Information” with debugging information, you can set a new breakpoint at line 7 by running the following command:

```
(gdb) break 7
Breakpoint 2 at 0x4004e3: file fibonacci.c, line 7.
```

To remove this breakpoint, type:

```
(gdb) clear 7
Deleted breakpoint 2
```

7.6. Starting Execution

To start execution of the program you are debugging, run the following command:

```
run
```

If the program accepts any command line arguments, you can provide them as arguments to the `run` command:

```
run argument...
```

The execution stops when a first breakpoint (if any) is reached, when an error occurs, or when the program terminates.

Example 7.8. Executing the fibonacci Binary File

Assuming that you have followed the instructions in Example 7.5, “Setting a New Breakpoint”, you can execute the `fibonacci` binary file by running the following command:

```
(gdb) run
Starting program: /home/john/fibonacci
Breakpoint 1, main (argc=1, argv=0x7fffffffe4d8) at fibonacci.c:10
10          printf("%ld ", b);
```

7.7. Displaying Current Values

The `gdb` utility allows you to display the value of almost anything that is relevant to the program, from a variable of any complexity to a valid expression or even a library function. However, the most common task is to display the value of a variable.

To display the current value of a certain variable, run the following command:
Example 7.9. Displaying the Current Values of Variables

Assuming that you have followed the instructions in Example 7.8, “Executing the fibonacci Binary File” and the execution of the fibonacci binary stopped after reaching the breakpoint at line 10, you can display the current values of variables a and b as follows:

(gdb) print a
$1 = 0
(gdb) print b
$2 = 1

7.8. Continuing Execution

To resume the execution of the program you are debugging after it reached a breakpoint, run the following command:

continue

The execution stops again when another breakpoint is reached. To skip a certain number of breakpoints (typically when you are debugging a loop), you can run the continue command in the following form:

continue number

The gdb utility also allows you to stop the execution after executing a single line of code. To do so, run:

step

Finally, you can execute a certain number of lines by using the step command in the following form:

step number
Example 7.10. Continuing the Execution of the fibonacci Binary File

Assuming that you have followed the instructions in Example 7.8, “Executing the fibonacci Binary File” and the execution of the fibonacci binary stopped after reaching the breakpoint at line 10, you can resume the execution by running the following command:

```
(gdb) continue
Continuing.
```

Breakpoint 1, main (argc=1, argv=0x7fffffffe4d8) at fibonacci.c:10
10          printf("%ld ", b);

The execution stops the next time the breakpoint is reached. To execute next three lines of code, type:

```
(gdb) step 3
13          b = sum;
```

This allows you to verify the current value of the sum variable before it is assigned to b:

```
(gdb) print sum
$3 = 2
```

7.9. Additional Resources

A detailed description of the GNU Debugger and all its features is beyond the scope of this book. For more information, see the resources listed below.

Online Documentation

- Red Hat Enterprise Linux 6 Developer Guide — The Developer Guide for Red Hat Enterprise Linux 6 provides more information on the GNU Debugger and debugging.
- GDB Documentation — The official GDB documentation includes the GDB User Manual and other reference material.

See Also

- Section A.6, “Changes in GDB” provides a comprehensive list of features and improvements over the Red Hat Enterprise Linux system version of the GNU Debugger and the version distributed in the previous release of Red Hat Developer Toolset.
- Chapter 1, Red Hat Developer Toolset provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- Chapter 2, Eclipse provides a general introduction to the Eclipse development environment, and describes how to use it with the tools from Red Hat Developer Toolset.
- Chapter 3, GNU Compiler Collection (GCC) provides further information on how to compile programs written in C, C++, and Fortran.
- Chapter 8, strace documents how to use the strace utility to monitor system calls that a program uses and signals it receives.
- Chapter 9, memstomp documents how to use the memstomp utility to identify calls to library functions with overlapping memory regions that are not allowed by various standards.
Chapter 8. strace

strace is a diagnostic and debugging tool for the command line that can be used to trace system calls that are made and received by a running process. It records the name of each system call, its arguments, and its return value, as well as signals received by the process and other interactions with the kernel, and prints this record to standard error output or a selected file.

Red Hat Developer Toolset is distributed with strace 4.7.

8.1. Installing strace

In Red Hat Enterprise Linux, the strace utility is provided by the devtoolset-2-strace package and is automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

8.2. Using strace

To run the strace utility on a program you want to analyze, type the following at a shell prompt:

```
scl enable devtoolset-2 'strace program [argument...]'
```

Replace program with the name of the program you want to analyze, and argument with any command line options and arguments you want to supply to this program. Alternatively, you can run the utility on an already running process by using the -p command line option followed by the process ID:

```
scl enable devtoolset-2 'strace -p process_id'
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset strace as default:

```
scl enable devtoolset-2 'bash'
```

To verify the version of strace you are using at any point, type the following at a shell prompt:

```
which strace
```

Red Hat Developer Toolset's strace executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset strace:

```
strace -V
```

8.2.1. Redirecting Output to a File

By default, strace prints the name of each system call, its arguments and the return value to standard error output. To redirect this output to a file, use the -o command line option followed by the file name:
Replace `file_name` with the name of the file.

**Example 8.1. Redirecting Output to a File**

Consider a slightly modified version of the `fibonacci` file from Example 7.1, “Compiling a C Program With Debugging Information”. This executable file displays the Fibonacci sequence and optionally allows you to specify how many members of this sequence to list. To run the `strace` utility on this file and redirect the trace output to `fibonacci.log`, type:

```
~]$ scl enable devtoolset-2 'strace -o fibonacci.log ./fibonacci 20'
1 1 2 3 5 8 13 21 34 55 89 144 233 377 610 987 1597 2584 4181 6765
```

This creates a new plain-text file called `fibonacci.log` in the current working directory.

### 8.2.2. Tracing Selected System Calls

To trace only a selected set of system calls, run the `strace` utility with the `-e` command line option:

```
scl enable devtoolset-2 'strace -e expression program [argument...]'
```

Replace `expression` with a comma-separated list of system calls to trace or any of the keywords listed in Table 8.1, “Commonly Used Values of the -e Option”. For a detailed description of all available values, see the `strace(1)` manual page.

#### Table 8.1. Commonly Used Values of the -e Option

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>System calls that accept a file name as an argument.</td>
</tr>
<tr>
<td>process</td>
<td>System calls that are related to process management.</td>
</tr>
<tr>
<td>network</td>
<td>System calls that are related to networking.</td>
</tr>
<tr>
<td>signal</td>
<td>System calls that are related to signal management.</td>
</tr>
<tr>
<td>ipc</td>
<td>System calls that are related to inter-process communication (IPC).</td>
</tr>
<tr>
<td>desc</td>
<td>System calls that are related to file descriptors.</td>
</tr>
</tbody>
</table>
Example 8.2. Tracing Selected System Calls

Consider the employee file from Example 9.1, "Using memstomp". To run the strace utility on this executable file and trace only the mmap and munmap system calls, type:

```
~$ scl enable devtoolset-2 'strace -e mmap,munmap ./employee'
mmap(NULL, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) =
 0x7f896c744000
mmap(NULL, 61239, PROT_READ, MAP_PRIVATE, 3, 0) = 0x7f896c735000
mmap(0x3146a00000, 3745960, PROT_READ|PROT_EXEC, MAP_PRIVATE|MAP_DENYWRITE, 3,
  0) = 0x3146a00000
mmap(0x3146d89000, 20480, PROT_READ|PROT_WRITE,
  MAP_PRIVATE|MAP_FIXED|MAP_DENYWRITE, 3, 0x189000) = 0x3146d89000
mmap(0x3146d8e000, 18600, PROT_READ|PROT_WRITE,
  MAP_PRIVATE|MAP_FIXED|MAP_ANONYMOUS, -1, 0) = 0x3146d8e000
mmap(NULL, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) =
 0x7f896c734000
mmap(NULL, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) =
 0x7f896c733000
mmap(NULL, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) =
 0x7f896c732000
munmap(0x7f896c735000, 61239)           = 0
mmap(NULL, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) =
 0x7f896c743000
John,john@example.comDoe,
+++ exited with 0 +++
```

8.2.3. Displaying Time Stamps

To prefix each line of the trace with the exact time of the day in hours, minutes, and seconds, run the strace utility with the -t command line option:

```
scl enable devtoolset-2 'strace -t program [argument...]'
```

To also display milliseconds, supply the -t option twice:

```
scl enable devtoolset-2 'strace -tt program [argument...]'
```

To prefix each line of the trace with the time required to execute the respective system call, use the -r command line option:

```
scl enable devtoolset-2 'strace -r program [argument...]'
```
Example 8.3. Displaying Time Stamps

Consider an executable file named `pwd`. To run the `strace` utility on this file and include time stamps in the output, type:

```bash
~]$ scl enable devtoolset-2 'strace -tt ./pwd'
19:43:28.011815 execve("./pwd", ["./pwd"], /* 36 vars */) = 0
19:43:28.012128 brk(0) = 0xcd3000
19:43:28.012174 mmap(NULL, 4096, PROT_READ|PROT_WRITE,
  MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) = 0x7fc869cb0000
19:43:28.012427 open("/etc/ld.so.cache", O_RDONLY) = 3
19:43:28.012446 fstat(3, {st_mode=S_IFREG|0644, st_size=61239, ...}) = 0
19:43:28.012464 mmap(NULL, 61239, PROT_READ, MAP_PRIVATE, 3, 0) =
  0x7fc869ca1000
19:43:28.012483 close(3) = 0
... 19:43:28.013410 +++ exited with 0 +++
```

8.2.4. Displaying a Summary

To display a summary of how much time was required to execute each system call, how many times the system calls were executed, and how many errors were encountered during their execution, run the `strace` utility with the `-c` command line option:

```bash
scl enable devtoolset-2 'strace -c program [argument...]'  
```

Example 8.4. Displaying a Summary

Consider an executable file named `lsblk`. To run the `strace` utility on this file and display a trace summary, type:

```bash
~]$ scl enable devtoolset-2 'strace -c ./lsblk > /dev/null'
% time seconds  usecs/call  calls  errors syscall
---------- ----------- ----------- --------- --------- ----------------
 80.88 0.000055 1 106 16 open
19.12 0.000013 0 140 munmap
 0.00 0.000000 0 148 read
 0.00 0.000000 0  1 write
 0.00 0.000000 0 258 close
 0.00 0.000000 0  37 stat
   ... 
---------- ----------- ----------- --------- --------- ----------------
100.00 0.000068 1790  35 total
```

8.3. Additional Resources

A detailed description of strace and its features is beyond the scope of this book. For more information, see the resources listed below.

Installed Documentation
strace(1) — The manual page for the strace utility provides detailed information about its usage.
To display the manual page for the version included in Red Hat Developer Toolset, type:

```
scl enable devtoolset-2 'man strace'
```

See Also

- **Section A.7, “Changes in strace”** provides a comprehensive list of features and improvements over the Red Hat Enterprise Linux system version of strace.
- **Chapter 1, Red Hat Developer Toolset** provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- **Chapter 7, GNU Debugger (GDB)** provides information on how to debug programs written in C, C++, and Fortran.
- **Chapter 9, memstomp** documents how to use the memstomp utility to identify calls to library functions with overlapping memory regions that are not allowed by various standards.
memstomp is a command line tool that can be used to identify function calls with overlapping memory regions in situations when such an overlap is not permitted by various standards. It intercepts calls to the library functions listed in Table 9.1, “Function Calls Inspected by memstomp” and for each memory overlap, it displays a detailed backtrace to help you debug the problem.

Similarly to Valgrind, the memstomp utility inspects applications without the need to recompile them. However, it is much faster than this tool and therefore serves as a convenient alternative to it.

Red Hat Developer Toolset is distributed with memstomp 0.1.4.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>

<td>wcsncat</td>
<td>The wide-character equivalent of the strncat() function that appends a maximum of $n$ wide characters from one array to another while overwriting the terminating null byte of the second wide-character string and adding a new one at its end. It returns a pointer to the new string.</td>
</tr>
</tbody>
</table>
9.1. Installing memstomp

In Red Hat Developer Toolset, the memstomp utility is provided by the devtoolset-2-memstomp package and is automatically installed with devtoolset-2-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

9.2. Using memstomp

To run the memstomp utility on a program you want to analyze, type the following at a shell prompt:

```
scl enable devtoolset-2 'memstomp program [argument...]'```

To immediately terminate the analyzed program when a problem is detected, run the utility with the --kill (or -k for short) command line option:

```
scl enable devtoolset-2 'memstomp --kill program [argument...]'```

The use of the --kill option is especially recommended if you are analyzing a multi-threaded program; the internal implementation of backtraces is not thread-safe and running the memstomp utility on a multi-threaded program without this command line option can therefore produce unreliable results.

Additionally, if you have compiled the analyzed program with the debugging information or this debugging information is available to you, you can use the --debug-info (or -d) command line option to produce a more detailed backtrace:

```
scl enable devtoolset-2 'memstomp --debug-info program [argument...]'```

For detailed instructions on how to compile your program with the debugging information built in the binary file, see Section 7.2, “Preparing a Program for Debugging”. For information on how to install debugging information for any of the Red Hat Developer Toolset packages, see Section 1.5.4, “Installing Debugging Information”.

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset memstomp as default:

```
scl enable devtoolset-2 'bash'```
Example 9.1. Using memstomp

In the current working directory, create a source file named `employee.c` with the following contents:

```c
#include <stdio.h>
#include <string.h>

#define BUFSIZE 80

int main(int argc, char *argv[]) {
    char employee[BUFSIZE] = "John,Doe,john@example.com";
    char name[BUFSIZE] = {0};
    char surname[BUFSIZE] = {0};
    char *email;
    size_t length;

    /* Extract the information: */
    memccpy(name, employee, ',', BUFSIZE);
    length = strlen(name);
    memccpy(surname, employee + length, ',', BUFSIZE);
    length += strlen(surname);
    email = employee + length;

    /* Compose the new entry: */
    strcat(employee, surname);
    strcpy(employee, name);
    strcat(employee, email);

    /* Print the result: */
    puts(employee);

    return 0;
}
```

Compile this program into a binary file named `employee` by using the following command:

```
~]$ scl enable devtoolset-2 'gcc -rdynamic -g -o employee employee.c'
```

To identify erroneous function calls with overlapping memory regions, type:

```
~]$ scl enable devtoolset-2 'memstomp --debug-info ./employee'
```

`memstomp: 0.1.4 successfully initialized for process employee (pid 14887).`
9.3. Additional Resources

A detailed description of `memstomp` and its features is beyond the scope of this book. For more information, see the resources listed below.

Installed Documentation

- `memstomp(1)` — The manual page for the `memstomp` utility provides detailed information about its usage. To display the manual page for the version included in Red Hat Developer Toolset, type:

```bash
scl enable devtoolset-2 'man memstomp'
```

Part V. Performance Monitoring Tools
Chapter 10. SystemTap

SystemTap is a tracing and probing tool that allows users to monitor the activities of the entire system without needing to instrument, recompile, install, and reboot. It is programmable with a custom scripting language, which gives it expressiveness (to trace, filter, and analyze) and reach (to look into the running kernel and applications).

SystemTap can monitor various types of events, such as function calls within the kernel or applications, timers, tracepoints, performance counters, and so on. Some included example scripts produce output similar to `netstat`, `ps`, `top`, and `iostat`, others include pretty-printed function callgraph traces or tools for working around security bugs.

Red Hat Developer Toolset is distributed with SystemTap 2.1.

Table 10.1. Tools Distributed with SystemTap for Red Hat Developer Toolset

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stap</td>
<td>Translates probing instructions into C code, builds a kernel module, and loads it into a running Linux kernel.</td>
</tr>
<tr>
<td>staprun</td>
<td>Loads, unloads, attaches to, and detaches from kernel modules built with the stap utility.</td>

<td>Merges per-CPU files. This script is automatically executed when the stap utility is executed with the <code>-b</code> command line option.</td>
</tr>
<tr>
<td>stap-report</td>
<td>Gathers important information about the system for the purpose of reporting a bug in SystemTap.</td>
</tr>
</tbody>
</table>

10.1. Installing SystemTap

In Red Hat Developer Toolset, SystemTap is provided by the `devtoolset-2-systemtap` package and is automatically installed with `devtoolset-2-perftools` as described in Section 1.5, “Installing Red Hat Developer Toolset”.

In order to place instrumentation into the Linux kernel, SystemTap may also require installation of additional packages with debugging information. To determine which packages to install, run the `stap-prep` utility as follows:

```
scl enable devtoolset-2 'stap-prep'
```

Note that if you execute this command as the root user, the utility automatically offers the packages for installation. For more information on how to install these packages on your system, see the Red Hat Enterprise Linux SystemTap Beginners Guide.

10.2. Using SystemTap

To execute any of the tools that are part of SystemTap, type the following at a shell prompt:

```
scl enable devtoolset-2 'tool [option...]'
```
See Table 10.1, “Tools Distributed with SystemTap for Red Hat Developer Toolset” for a list of tools that are distributed with SystemTap. For example, to run the stap tool to build an instrumentation module, type:

```
scl enable devtoolset-2 'stap [option...] argument...'
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset SystemTap as default:

```
scl enable devtoolset-2 'bash'
```

Note

To verify the version of SystemTap you are using at any point, type the following at a shell prompt:

```
which stap
```

Red Hat Developer Toolset's stap executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset SystemTap:

```
stap -V
```

10.3. Additional Resources

A detailed description of SystemTap and its features is beyond the scope of this book. For more information, see the resources listed below.

Installed Documentation

- stap(1) — The manual page for the stap command provides detailed information on its usage, as well as references to other related manual pages. To display the manual page for the version included in Red Hat Developer Toolset, type:

```
scl enable devtoolset-2 'man stap'
```

- staprun(8) — The manual page for the staprun command provides detailed information on its usage. To display the manual page for the version included in Red Hat Developer Toolset, type:

```
scl enable devtoolset-2 'man staprun'
```

- **Chapter 13, Dyninst** documents how to use the Dyninst library to instrument a user-space executable.
Chapter 11. Valgrind

Valgrind is an instrumentation framework that ships with a number of tools to profile applications. It can be used to detect various memory errors and memory management problems, such as the use of uninitialized memory or improper allocation and freeing of memory, or to identify the use of improper arguments in system calls. For a complete list of profiling tools that are distributed with the Red Hat Developer Toolset version of Valgrind, see Table 11.1, “Tools Distributed with Valgrind for Red Hat Developer Toolset”.

Valgrind profiles an application by rewriting it and instrumenting the rewritten binary. This allows you to profile your application without the need to recompile it, but it also makes Valgrind significantly slower than other profilers, especially when performing extremely detailed runs. It is therefore not suited to debugging time-specific issues, or kernel-space debugging.

Red Hat Developer Toolset is distributed with Valgrind 3.8.1. This version is more recent than the version included in Red Hat Enterprise Linux and provides numerous bug fixes and enhancements.

Table 11.1. Tools Distributed with Valgrind for Red Hat Developer Toolset

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memcheck</td>
<td>Detects memory management problems by intercepting system calls and checking all read and write operations.</td>

<td>Monitors heap and stack usage.</td>
</tr>
</tbody>
</table>

11.1. Installing Valgrind

In Red Hat Developer Toolset, Valgrind is provided by the devtoolset-2-valgrind package and is automatically installed with devtoolset-2-perftools. If you intend to use Valgrind to profile parallel programs that use the Message Passing Interface (MPI) protocol, also install the devtoolset-2-valgrind-openmpi package by typing the following at a shell prompt as root:

```
yum install devtoolset-2-valgrind-openmpi
```

For detailed instructions on how to install Red Hat Developer Toolset and related packages to your system, see Section 1.5, “Installing Red Hat Developer Toolset”.

11.2. Using Valgrind

To run any of the Valgrind tools on a program you want to profile, type the following at a shell prompt:

```
scl enable devtoolset-2 'valgrind [--tool=tool] program [argument...]'
```

See Table 11.1, “Tools Distributed with Valgrind for Red Hat Developer Toolset” for a list of tools that
are distributed with Valgrind. The argument of the \texttt{--tool} command line option must be specified in lower case, and if this option is omitted, Valgrind uses \texttt{Memcheck} by default. For example, to run Cachegrind on a program to identify the sources of cache misses, type:

\begin{verbatim}
scl enable devtoolset-2 'valgrind --tool=cachegrind program [argument...]'\end{verbatim}

Note that you can execute any command using the \texttt{scl} utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset Valgrind as default:

\begin{verbatim}
scl enable devtoolset-2 'bash'\end{verbatim}

To verify the version of Valgrind you are using at any point, type the following at a shell prompt:

\begin{verbatim}
which valgrind\end{verbatim}

Red Hat Developer Toolset's \texttt{valgrind} executable path will begin with \texttt{/opt}. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset Valgrind:

\begin{verbatim}
valgrind --version\end{verbatim}

### 11.3. Additional Resources

A detailed description of Valgrind and its features is beyond the scope of this book. For more information, see the resources listed below.

**Installed Documentation**

- \texttt{valgrind(1)} — The manual page for the \texttt{valgrind} utility provides detailed information on how to use Valgrind. To display the manual page for the version included in Red Hat Developer Toolset, type:

\begin{verbatim}
scl enable devtoolset-2 'man valgrind'\end{verbatim}

**Online Documentation**

- Red Hat Enterprise Linux 6 Performance Tuning Guide — The Performance Tuning Guide for Red Hat Enterprise Linux 6 provides more detailed information about using Valgrind to profile applications.

**See Also**
Section A.10, “Changes in Valgrind” provides a comprehensive list of features and improvements over the Red Hat Enterprise Linux system version of Valgrind and the version distributed in the previous release of Red Hat Developer Toolset.

Chapter 1, Red Hat Developer Toolset provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.

Chapter 9, memstomp documents how to use the memstomp utility to identify calls to library functions with overlapping memory regions that are not allowed by various standards.

Chapter 10, SystemTap provides an introduction to SystemTap and explains how to use it to monitor the activities of a running system.

Chapter 12, OProfile explains how to use OProfile to determine which sections of code consume the greatest amount of CPU time and why.

Chapter 13, Dyninst documents how to use the Dyninst library to instrument a user-space executable.
Chapter 12. OProfile

OProfile is a low overhead, system-wide profiler that uses the performance monitoring hardware on the processor to retrieve information about the kernel and executables on the system, such as when memory is referenced, the number of level 2 cache (L2) requests, and the number of hardware interrupts received. It consists of a configuration utility, a daemon for collecting data, and a number of tools that can be used to transform the data into a human-readable form. For a complete list of tools that are distributed with the Red Hat Developer Toolset version of OProfile, see Table 12.1, “Tools Distributed with OProfile for Red Hat Developer Toolset”.

OProfile profiles an application without adding any instrumentation by recording the details of every nth event. This allows it to consume fewer resources than Valgrind, but also causes its samples to be less precise. Unlike Valgrind, which only collects data for a single process and its children in user-space, OProfile is well suited to collect system-wide data on both user-space and kernel-space processes, and requires root privileges to run.

Red Hat Developer Toolset is distributed with OProfile 0.9.8. This version is more recent than the version included in Red Hat Enterprise Linux and provides numerous bug fixes and enhancements.

Table 12.1. Tools Distributed with OProfile for Red Hat Developer Toolset

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oprofiled</td>
<td>The OProfile daemon that collects profiling data.</td>
</tr>
<tr>
<td>opcontrol</td>
<td>Starts, stops, and configures the OProfile daemon.</td>
</tr>
<tr>
<td>opannotate</td>
<td>Generates an annotated source file or assembly listing form the profiling data.</td>
</tr>
<tr>
<td>oparchive</td>
<td>Generates a directory containing executable, debug, and sample files.</td>
</tr>
<tr>
<td>opgprof</td>
<td>Generates a summary of a profiling session in a format compatible with gprof.</td>
</tr>
<tr>
<td>ophelp</td>
<td>Displays a list of available events.</td>
</tr>
<tr>
<td>opimport</td>
<td>Converts a sample database file from a foreign binary format to the native format.</td>
</tr>
<tr>
<td>opjitconv</td>
<td>Converts a just-in-time (JIT) dump file to the Executable and Linkable Format (ELF).</td>
</tr>
<tr>
<td>opreport</td>
<td>Generates image and symbol summaries of a profiling session.</td>
</tr>
</tbody>
</table>

12.1. Installing OProfile

In Red Hat Developer Toolset, OProfile is provided by the devtoolset-2-oprofile package and is automatically installed with devtoolset-2-perftools as described in Section 1.5, “Installing Red Hat Developer Toolset”.

12.2. Using OProfile

To run any of the tools that are distributed with OProfile, type the following at a shell prompt as root:

```
scl enable devtoolset-2 'tool [option...]'
```

See Table 12.1, “Tools Distributed with OProfile for Red Hat Developer Toolset” for a list of tools that are distributed with Valgrind. For example, to use the ophelp command to list available events in the
For example, to use the `ophelp` command to list available events in the XML format, type:

```
scl enable devtoolset-2 'ophelp -X'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset OProfile as default:

```
scl enable devtoolset-2 'bash'
```

**Note**

To verify the version of OProfile you are using at any point, type the following at a shell prompt:

```
which opcontrol
```

Red Hat Developer Toolset's `opcontrol` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset OProfile:

```
opcontrol --version
```

### 12.3. Additional Resources

A detailed description of OProfile and its features is beyond the scope of this book. For more information, see the resources listed below.

**Installed Documentation**

- `oprofile(1)` — The manual page named `oprofile` provides an overview of OProfile and available tools. To display the manual page for the version included in Red Hat Developer Toolset, type:

  ```
scl enable devtoolset-2 'man oprofile'
  ```

- `opannotate(1), oparchive(1), opcontrol(1), opgprof(1), ophelp(1), opimport(1), opreport(1)` — Manual pages for various tools distributed with OProfile provide more information on their respective usage. To display the manual page for the version included in Red Hat Developer Toolset, type:

  ```
scl enable devtoolset-2 'man tool'
  ```

**Online Documentation**

See Also

- **Section A.9, “Changes in OProfile”** provides a comprehensive list of changes and improvements over the Red Hat Enterprise Linux system version of OProfile and the version distributed in the previous release of Red Hat Developer Toolset.

- **Chapter 1, Red Hat Developer Toolset** provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.

- **Chapter 10, SystemTap** provides an introduction to SystemTap and explains how to use it to monitor the activities of a running system.

- **Chapter 11, Valgrind** explains how to use Valgrind to profile applications and detect memory errors and memory management problems, such as the use of uninitialized memory, improper allocation and freeing of memory, and the use of improper arguments in system calls.

- **Chapter 13, Dyninst** documents how to use the Dyninst library to instrument a user-space executable.
Chapter 13. Dyninst

The Dyninst library provides an application programming interface (API) for instrumenting and working with user-space executables during their execution. It can be used to insert code into a running program, change certain subroutine calls, or even remove them from the program, and serves as a valuable debugging and performance monitoring tool. The Dyninst API is also commonly used along with SystemTap to allow non-root users to instrument user-space executables.

Red Hat Developer Toolset is distributed with Dyninst 8.0.

13.1. Installing Dyninst

In Red Hat Developer Toolset, the Dyninst library is provided by the devtoolset-2-dyninst package and is automatically installed with devtoolset-2-perftools as described in Section 1.5, “Installing Red Hat Developer Toolset”. In addition, it is recommended that you also install the GNU Compiler Collection provided by the devtoolset-2-toolchain package.

If you intend to write a custom instrumentation for binaries, install the relevant header files by running the following command as root:

```
yum install devtoolset-2-dyninst-devel
```

You can also install API documentation for this library by typing the following at a shell prompt as root:

```
yum install devtoolset-2-dyninst-doc
```

For a complete list of documents that are included in the devtoolset-2-dyninst-doc package, see Section 13.3, “Additional Resources”. For detailed instructions on how to install optional packages to your system, see Section 1.5, “Installing Red Hat Developer Toolset”.

13.2. Using Dyninst

13.2.1. Using Dyninst with SystemTap

To use Dyninst along with SystemTap to allow non-root users to instrument user-space executables, run the stap command with the --dyninst (or --runtime=dyninst) command line option. This tells stap to translate a SystemTap script into C code that uses the Dyninst library, compile this C code into a shared library, and then load the shared library and run the script. Note that when executed like this, the stap command also requires the -c or -x command line option to be specified.

To use the Dyninst runtime to instrument an executable file, type the following at a shell prompt:

```
scl enable devtoolset-2 'stap --dyninst -c command [option...] argument...'
```

Similarly, to use the Dyninst runtime to instrument a user’s process, type:

```
scl enable devtoolset-2 'stap --dyninst -x process_id [option...] argument...'
```

See Chapter 10, SystemTap for more information about the Red Hat Developer Toolset version of SystemTap. For a general introduction to SystemTap and its usage, see the SystemTap Beginners Guide for Red Hat Enterprise Linux.
13.2.2. Using Dyninst as a Stand-alone Application

Before using the Dyninst library as a stand-alone application, set the value of the `DYNINSTAPI_RT_LIB` environment variable to the path to the runtime library file. If you are running a 64-bit system, you can do so by typing the following at a shell prompt:

```bash
export DYNINSTAPI_RT_LIB=/opt/rh/devtoolset-2/root/usr/lib64/dyninst/libdyninstAPI_RT.so.8.0
```

If you are running a 32-bit system, type:

```bash
export DYNINSTAPI_RT_LIB=/opt/rh/devtoolset-2/root/usr/lib/dyninst/libdyninstAPI_RT.so.8.0
```

This sets the `DYNINSTAPI_RT_LIB` environment variable in the current shell session.

Example 13.1, “Using Dyninst as a Stand-alone Application” illustrates how to write and build a program to monitor the execution of a user-space process. For a detailed explanation of how to use Dyninst, see the resources listed in Section 13.3, “Additional Resources.”
Example 13.1. Using Dyninst as a Stand-alone Application

Consider a source file named `exercise.c` that has the following contents:

```c
#include <stdio.h>

void print_iteration(int value) {
    printf("Iteration number %d
", value);
}

int main(int argc, char **argv) {
    int i;
    printf("Enter the starting number: ");
    scanf("%d", &i);
    for(; i>0; --i)
        print_iteration(i);
    return 0;
}
```

This program prompts the user to enter a starting number and then counts down to 1, calling the `print_iteration()` function for each iteration in order to print the number to standard output. Now consider another source file named `count.c` with the following contents:
#include <stdio.h>
#include <fcntl.h>
#include "BPatch.h"
#include "BPatch_process.h"
#include "BPatch_function.h"
#include "BPatch_Vector.h"
#include "BPatch_thread.h"
#include "BPatch_point.h"

void usage() {
    fprintf(stderr, "Usage: count <process_id> <function>\n");
}

// Global information for counter
BPatch_variableExpr *counter = NULL;

void createCounter(BPatch_process *app, BPatch_image *appImage) {
    int zero = 0;
    counter = app->malloc(*appImage->findType("int"));
    counter->writeValue(&zero);
}

bool interceptfunc(BPatch_process *app, BPatch_image *appImage, char *funcName) {
    BPatch_Vector<BPatch_function *> func;
    appImage->findFunction(funcName, func);
    if (func.size() == 0) {
        fprintf(stderr, "Unable to find function to instrument()\n");
        exit (-1);
    }
    BPatch_Vector<BPatch_snippet *> incCount;
    BPatch_Vector<BPatch_point *> *points;
    points = func[0]->findPoint(BPatch_entry);
    if ((*points).size() == 0) {
        exit (-1);
    }
    BPatch_arithExpr counterPlusOne(BPatch_plus, *counter, BPatch_constExpr(1));
    BPatch_arithExpr addCounter(BPatch_assign, *counter, counterPlusOne);
    return app->insertSnippet(addCounter, *points);
}

void printCount(BPatch_thread *thread, BPatch_exitType) {
    int val = 0;
    counter->readValue(&val, sizeof(int));
    fprintf(stderr, "Function executed %d times.\n", val);
}

BPatch bpatch;

int main(int argc, char *argv[]) {
    int pid;
    if (argc != 3) {
        usage();
        exit(1);
    }
    pid = atoi(argv[1]);
BPatch_process *app = bpatch.processAttach(NULL, pid);
if (!app) exit (-1);
BPatch_image *appImage = app->getImage();
createCounter(app, appImage);
fprintf(stderr, "Finding function %s(): ", argv[2]);
BPatch_Vector<BPatch_function*> countFuncs;
fprintf(stderr, "OK\nInstrumenting function %s(): ", argv[2]);
interceptfunc(app, appImage, argv[2]);
bpatch.registerExitCallback(printCount);
fprintf(stderr, "OK\nWaiting for process %d to exit...\n", pid);
app->continueExecution();
while (!app->isTerminated())
    bpatch.waitForStatusChange();
return 0;
}

This program accepts a process ID and a function name as command line arguments and then prints the total number of times the function was called during the execution of the process. You can use the following Makefile to build these two files:

```
DTS     = /opt/rh/devtoolset-2/root
CXXFLAGS = -g -I$(DTS)/usr/include/dyninst
LBITS   := $(shell getconf LONG_BIT)
ifeq ($(LBITS),64)
    DYINSTLIBLES = $(DTS)/usr/lib64/dyninst
else
    DYINSTLIBLES = $(DTS)/usr/lib/dyninst
endif

.PHONY: all
all: count exercise
count: count.C
    g++ $(CXXFLAGS) count.C -I /usr/include/dyninst -c
g++ $(CXXFLAGS) count.o -L $(DYINSTLIBLES) -ldyninstAPI -o count
exercise: exercise.C
    g++ $(CXXFLAGS) exercise.C -o exercise

.PHONY: clean
clean:
    rm -rf *~ *.o count exercise
```

To compile the two programs on the command line using the g++ compiler from Red Hat Developer Toolset, run the make utility as follows:

```
~]$ scl enable devtoolset-2 make
g++ -g -I/opt/rh/devtoolset-2/root/usr/include/dyninst count.C -c
g++ -g -I/opt/rh/devtoolset-2/root/usr/include/dyninst count.o -L
    /opt/rh/devtoolset-2/root/usr/lib64/dyninst -ldyninstAPI -o count
g++ -g -I/opt/rh/devtoolset-2/root/usr/include/dyninst exercise.C -o exercise
```

This creates new binary files called exercise and count in the current working directory.

In one shell session, execute the exercise binary file as follows and wait for it to prompt you to enter the starting number:
Enter the starting number:

Do not enter this number. Instead, start another shell session and type the following at its prompt to set the DYNINSTAPI_RT_LIB environment variable and execute the count binary file:

```
~$ export DYNINSTAPI_RT_LIB=/opt/rh/devtoolset-2/root/usr/lib64/dyninst/libdyninstAPI_RT.so.8.0
~$ ./count `pidof exercise` print_iteration
  Finding function print_iteration(): OK
  Instrumenting function print_iteration(): OK
  Waiting for process 8607 to exit...
```

Now switch back to the first shell session and enter the starting number as requested by the exercise program. For example:

```
Enter the starting number: 5
  Iteration number 5
  Iteration number 4
  Iteration number 3
  Iteration number 2
  Iteration number 1
```

When the exercise program terminates, the count program displays the number of times the print_iteration() function was executed:

```
Function executed 5 times.
```

### 13.3. Additional Resources

A detailed description of Dyninst and its features is beyond the scope of this book. For more information, see the resources listed below.

#### Installed Documentation

The devtoolset-2-dyninst-doc package installs the following documents in the `/opt/rh/devtoolset-2/root/usr/share/doc/devtoolset-2-dyninst-doc-8.0/` directory:

- **DynC API Programmer’s Guide** — An introduction to DynC API is stored in the `dynC_API.pdf` file.
- **StackwalkerAPI Programmer’s Guide** — A detailed description of StackwalkerAPI is stored in the `stackwalker.pdf` file.
- **SymtabAPI Programmer’s Guide** — An introduction to SymtabAPI is stored in the `SymtabAPI.pdf` file.

For information on how to install this package on your system, see Section 13.1, “Installing Dyninst”.

Online Documentation

- Dyninst Home Page — The project home page provides links to additional documentation and related publications.
- Red Hat Enterprise Linux 6 SystemTap Tapset Reference — The SystemTap Tapset Reference for Red Hat Enterprise Linux 6 provides further details about SystemTap.
- Red Hat Enterprise Linux 5 SystemTap Tapset Reference — The SystemTap Tapset Reference for Red Hat Enterprise Linux 5 provides further details about SystemTap.

See Also

- Chapter 1, Red Hat Developer Toolset provides an overview of Red Hat Developer Toolset and more information on how to install it on your system.
- Chapter 10, SystemTap provides an introduction to SystemTap and explains how to use it to monitor the activities of a running system.
- Chapter 11, Valgrind explains how to use Valgrind to profile applications and detect memory errors and memory management problems, such as the use of uninitialized memory, improper allocation and freeing of memory, and the use of improper arguments in system calls.
- Chapter 12, OProfile explains how to use OProfile to determine which sections of code consume the greatest amount of CPU time and why.
Part VI. Getting Help
Chapter 14. Accessing Red Hat Product Documentation

Red Hat Product Documentation located at https://access.redhat.com/site/documentation/ serves as a central source of information. It is currently translated in 22 languages and for each product, it provides different kinds of books from release and technical notes to installation, user, and reference guides in HTML, PDF, and EPUB formats.

Below is a brief list of documents that are directly or indirectly relevant to this book.

### Red Hat Developer Toolset

- [Red Hat Developer Toolset 2.0 Release Notes](#) — The Release Notes for Red Hat Developer Toolset 2.0 provide more information about this product.

- [Red Hat Developer Toolset 2.0 Software Collections Guide](#) — The Software Collections Guide for Red Hat Developer Toolset 2.0 explains the concept of Software Collections and documents the `scl` tool.

### Red Hat Enterprise Linux

- [Red Hat Enterprise Linux 6 Developer Guide](#) — The Developer Guide for Red Hat Enterprise Linux 6 provides detailed information about libraries and runtime support, compiling and building, debugging, and profiling.

- [Red Hat Enterprise Linux 6 Installation Guide](#) — The Installation Guide for Red Hat Enterprise Linux 6 explains how to obtain, install, and update the system.

- [Red Hat Enterprise Linux 5 Installation Guide](#) — The Installation Guide for Red Hat Enterprise Linux 5 explains how to obtain, install, and update the system.

- [Red Hat Enterprise Linux 5 Deployment Guide](#) — The Deployment Guide for Red Hat Enterprise Linux 5 documents relevant information regarding the deployment, configuration, and administration of Red Hat Enterprise Linux 5.
Chapter 15. Accessing the Customer Portal

The Customer Portal is available to all Red Hat subscribers and can be accessed at https://access.redhat.com/home. This web page serves as a pointer to a vast number of resources but of most interest to developers are the Plan, Deploy, and Connect menus. These include links to all the resources needed during each stage of the development.

15.1. The Plan Menu

In the Plan menu are resources needed to plan a development project. These menu items provide proven resources to implement the best solution the first time. This includes:

**Webinars**

The Webinars page contains information on upcoming Red Hat and open source events around the world. Here you can register for upcoming webinars or watch archived ones on demand.

**Success Stories**

Read the success stories of other Red Hat customers to learn how leading organizations are finding unbeatable value, performance, security and reliability with Red Hat solutions.

**Product Documentation**

This provides a list of links to the various Red Hat documents, including books for Red Hat Enterprise Linux, Identity Management and Infrastructure, Red Hat Enterprise Storage, JBoss Enterprise Middleware, and System Management.

**Reference Architectures**

Reference Architectures contains a list of whitepapers that detail technical case studies of solutions that have been built, tested, and bench-marked by senior Red Hat engineers. They explain the capabilities and limitations of a given solution, as well as detailed notes on how to implement the solution.

**Evaluations & Demos**

You can download free evaluations of various Red Hat products from here, including Red Hat Enterprise Linux, Red Hat Enterprise Virtualization, Red Hat Storage Appliance, and JBoss Enterprise Middleware evaluations.
Certified Hardware

This section has information on what systems, components, and peripherals Red Hat Enterprise Linux 6, 5, and 4 support.

15.2. The Deploy Menu

In the Deploy menu are resources needed to deploy a development project. This includes:

Getting Started

The Getting Started page has links to information to help get up and running with Red Hat subscriptions, including product registration information, accessing your resources, and engaging in global support. It also has links to a Red Hat Welcome Kit and a Quick Guide to Red Hat Support.

Downloads

Here is where you can download all that Red Hat offers with descriptions of what each entails.

Activate a New Subscription

After purchasing a Red Hat subscription this is where you go to activate it. Note that the Activate a New Subscription section requires you to enter your Red Hat login and password.

Support Essentials

Here you can find a list of articles and group discussions, viewable by new posts, most popular, and recent comments, as well as the most recent Red Hat errata.

Security

Red Hat releases errata to address bugs, provide enhancements, or to fix security vulnerabilities. With each erratum an advisory is supplied to give the details of the issues being fixed, as well as how to obtain and install the required software packages. This section has information about the errata, including:

- Checking the security update policy and lifetime for all Red Hat products
- Getting the latest security updates for Red Hat products
- Getting notified of new security updates
Finding out if a specific CVE affects a Red Hat product
Reporting a security vulnerability
How we measure security vulnerabilities
Security Response Team mission and standards of service

Support
This is where all the information regarding Red Hat support can be found, including links for:

» Support Cases
» Support Programs
» Product Life Cycles
» Supported Environments
» Help & Assistance
» Site Help

15.3. The Connect Menu

The Connect menu allows you to connect to the industry's best engineers and collaborate with industry peers. This includes:

Knowledgebase
The Knowledgebase contains a large number of whitepapers on a variety of topics which can serve as another source of documentation for your project. Note that the Knowledgebase section requires you to enter your Red Hat login and password.

Groups
This section allows users to join a group to collaborate on the documents. They can also create and comment on discussions to interact with other customers, Red Hat support staff, and certified engineers. Note that the Groups section requires you to enter your Red Hat login and password.

Videos
A number of videos on how to get vital solutions, useful tips, product demonstrations, and inside information can be accessed from here. You can also rate and comment on all of the videos.
Tech Briefs

Tech briefs provide practical advice to help solve real-world problems with Red Hat products. Each tech brief provides a detailed use case covering best practices, how-to instructions, or detailed discussions on how to use Red Hat technology effectively, and are reviewed and tested by Red Hat engineers.

Source

This is the kernel source browser and contains links to all the kernel sources broken into each individual patch, unlike the kernel srpm which is shipped as one big patch. Note that the Source section requires you to enter your Red Hat login and password.

Support Cases

This is where users can view all their support cases, make changes or view any updates. Note that the Support Cases section requires you to enter your Red Hat login and password.
Chapter 16. Contacting Global Support Services

Unless you have a Self-Support subscription, when both the Red Hat Documentation website and Customer Portal fail to provide the answers to your questions, you can contact Global Support Services (GSS).

16.1. Gathering Required Information

Several items of information should be gathered before contacting GSS.

Background Information

Ensure you have the following background information at hand before calling GSS:

- Hardware type, make, and model on which the product runs
- Software version
- Latest upgrades
- Any recent changes to the system
- An explanation of the problem and the symptoms
- Any messages or significant information about the issue

Note

If you ever forget your Red Hat login information, it can be recovered at https://access.redhat.com/site/help/LoginAssistance.html.

Diagnostics

The diagnostics report for Red Hat Enterprise Linux is required as well. This report is also known as a sosreport and the program to create the report is provided by the sos package. To install the sos package and all its dependencies on your system, type the following at a shell prompt as root:

```bash
yum install sos
```

To generate the report, run as root:

```bash
sosreport
```

For more information, access the Knowledgebase article at https://access.redhat.com/kb/docs/DOC-3593.

Account and Contact Information

In order to help you, GSS requires your account information to customize their support, as well contact information to get back to you. When you contact GSS ensure you have your:

- Red Hat customer number or Red Hat Network (RHN) login name
- Company name
- Contact name
- Preferred method of contact (phone or email) and contact information (phone number or email address)
**Issue Severity**
Determining an issue's severity is important to allow the GSS team to prioritize their work. There are four levels of severity.

**Severity 1 (urgent)**
A problem that severely impacts your use of the software for production purposes. It halts your business operations and has no procedural work around.

**Severity 2 (high)**
A problem where the software is functioning but production is severely reduced. It causes a high impact to business operations and no work around exists.

**Severity 3 (medium)**
A problem that involves partial, non-critical loss of the use of the software. There is a medium to low impact on your business and business continues to function by utilizing a work around.

**Severity 4 (low)**
A general usage question, report of a documentation error, or a recommendation for a future product improvement.

For more information on determining the severity level of an issue, see [https://access.redhat.com/support/policy/severity](https://access.redhat.com/support/policy/severity).

Once the issue severity has been determined, submit a service request through the Customer Portal under the Connect option, or at [https://access.redhat.com/support/contact/technicalSupport.html](https://access.redhat.com/support/contact/technicalSupport.html). Note that you need your Red Hat login details in order to submit service requests.

If the severity is level 1 or 2, then follow up your service request with a phone call. Contact information and business hours are found at [https://access.redhat.com/support/contact/technicalSupport.html](https://access.redhat.com/support/contact/technicalSupport.html).

If you have a premium subscription, then after hours support is available for Severity 1 and 2 cases. Turn-around rates for both premium subscriptions and standard subscription can be found at [https://access.redhat.com/support/offerings/production/sla.html](https://access.redhat.com/support/offerings/production/sla.html).

**16.2. Escalating an Issue**
If you feel as though an issue is not being handled correctly or adequately, you can escalate it. There are two types of escalation:

**Technical escalation**
If an issue is not being resolved appropriately or if you need a more senior resource to attend to it.

**Management escalation**
If the issue has become more severe or you believe it requires a higher priority.

More information on escalation, including contacts, is available at
https://access.redhat.com/support/policy/mgt_escalation.html

16.3. Re-opening a Service Request
If more relevant information regarding a closed service request (such as the problem reoccurring), you can re-open it via the Red Hat Customer Portal at https://access.redhat.com/support/policy/mgt_escalation.html or by calling your local support center, the details of which can be found at https://access.redhat.com/support/contact/technicalSupport.html.

**Important**
In order to re-open a service request, you need the original service request number.

16.4. Additional Resources
For more information, see the resources listed below.

**Online Documentation**
- [Getting Started](#) — The Getting Started page serves as a starting point for people who purchased a Red Hat subscription, and offers the Red Hat Welcome Kit and Quick Guide to Red Hat Support for download.
- [How can a RHEL Self-Support subscription be used?](#) — A Knowledgebase article for customers with a Self-Support subscription.
- [Red Hat Global Support Services and public mailing lists](#) — A Knowledgebase article that answers frequent questions about public Red Hat mailing lists.
Changes in Version 2.0

The sections below document features and compatibility changes introduced in Red Hat Developer Toolset 2.0.

A.1. Changes in Eclipse

Red Hat Developer Toolset 2.0 is distributed with Eclipse 4.3 and a wide selection of plug-ins from the Eclipse Foundation's 2013 Eclipse 4.3 "Kepler" release, and provides a number of bug fixes and feature enhancements over the Red Hat Enterprise Linux system version. Below is a comprehensive list of new features compatibility changes in this release. For details on how to use these new features, see the built-in Eclipse documentation.

A.1.1. Changes Since Red Hat Enterprise Linux 6.4

The following features have been added since the release of the Eclipse Platform and native plug-ins included in Red Hat Enterprise Linux 6.4:

- The Eclipse Platform has been updated to from version 3.6 to 4.3. This new major release features a more flexible user interface based on Eclipse Modeling Framework (EMF), CSS-based themes, dependency injection, and more.
- The Eclipse C/C++ Development Toolkit (CDT) has been updated from version 7.0 to 8.2. This new major release includes:
  - a greatly enhanced indexer, both in terms of capabilities and speed;
  - improved GNU Debugger integration;
  - support for GNU Debugger's pretty-printing;
  - multi-process debugging;
  - project-less debugging;
  - enhanced refactoring;
  - code-checking capabilities;
  - an improved and more polished user interface.
- Mylyn, a set of task and application life cycle management plug-ins, has been updated from version 3.4 to 3.9. This update includes:
  - an enhanced task-focused interface and task editing;
  - a new Jenkins/Hudson connector;
  - enhanced Bugzilla and Trac connectors;
  - EPUB authoring tools.
- A new EGit plug-in has been added. This plug-in includes an Eclipse Team provider based on JGit, a Git implementation written entirely in Java, and adds support for the Git revision control system to the Eclipse user interface by introducing the History and Synchronize views, Compare and Quick Diff menu items, and various wizards to make it easier for developers to use this plug-in.
- New GCov integration has been added to allow the user to visualize GCov output in both summarized form and in file editors. As well, graphing capabilities for the data have been added.
- New GProf integration has been added to allow the user to view profiling information such as execution time and call graphs. As well, graphing capabilities for the data have been added.
- A new SystemTap integration plug-in has been added. This plug-in includes:
  - an editor for the .stp files with the autocomplete feature;
  - the Probe view with a list of probes that are available on the system;
  - the Function view with a list of functions that are available on the system and can be used in...
As well, this plug-in includes integration for running SystemTap scripts and viewing the results in a textual, tabular, and graphical manner. Note that the result sets are updated in a near-runtime way, which allows the user to use this plug-in for longer-running monitoring tasks.

- New kernel `perf` tool integration has been added. This plug-in uses the performance counters subsystem of the Linux kernel to profile applications, makes it easier to analyze the results by hyperlinking to the sources in the workspace projects, simplifies the `perf` tool configuration by selecting the counters to be used, and allows the user to run this tool remotely.

- A unified profiling launcher has been added to provide a single method to launch profiling. It allows the user to select a profiling category (Memory, Timing, or Coverage) and back ends for this category (such as OProfile, perf, or GProf for Timing).

- The C/C++ documentation plug-in has been enhanced to recognize and use `gtk-doc` generated documentation and to display it in the Eclipse Help Center.

- The OProfile plug-in has been enhanced to support root privilege authentication through `polkit`. This feature is configured automatically.

- The Valgrind plug-in now supports the Helgrind tool, which can be used to detect synchronization problems such as race conditions, deadlocks caused by incorrect locking order, or misuse of the POSIX `threads` API. When a problem is detected, the plug-in displays error markers on the corresponding lines in the source code.

### A.2. Changes in GCC

Red Hat Developer Toolset 2.0 is distributed with GCC 4.8, which provides a number of bug fixes and feature enhancements over the Red Hat Enterprise Linux system version and the version included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of new features and compatibility changes in this release.

#### A.2.1. Changes Since Red Hat Developer Toolset 1.1

The following features have been added since the release of GCC included in Red Hat Developer Toolset 1.1.

##### A.2.1.1. Caveats

**Aggressive Loop Optimizations**

The loop optimizer of GCC has been improved to use language constraints in order to derive bounds for the number of iterations of a loop. The bounds are then used as a guide to loop unrolling, peeling, and loop exit test optimizations.

The optimizations assume that the loop code does not invoke undefined behavior by, for example, causing signed integer overflows or making out-of-bound array accesses. For example, consider the following code fragment:

```c
unsigned int foo()
{
    unsigned int data_data[128];

    for (int fd = 0; fd < 128; ++fd)
        data_data[fd] = fd * (0x02000001); // error

    return data_data[0];
}
```
When the value of the `fd` variable is 64 or above, the `fd * 0x02000001` operation overflows, which is invalid in both C and C++ for signed integers. In the example above, GCC may generate incorrect code or enter an infinite loop.

To fix this error, use the appropriate casts when converting between signed and unsigned types to avoid overflows, for instance:

```
data_data[fd] = (uint32_t) fd * (0x02000001U); // ok
```

If necessary, this optimization can be turned off by using the new command line option `-fno-aggressive-loop-optimizations`.

### A.2.1.2. General Improvements and Changes

#### New Local Register Allocator

GCC 4.8 features a new Local Register Allocator (LRA), which replaces the 26-year old reload pass and improves the quality of generated code. The new local register allocator is meant to be simpler, easier to debug, and does a better job of register allocation.

#### AddressSanitizer

A fast memory error detector called AddressSanitizer has been added and can be enabled by using the `-fsanitize=address` command line option. It augments memory access instructions in order to detect use-after-free and out-of-bound accesses to objects on the heap.

#### ThreadSanitizer

A fast data race detector called ThreadSanitizer has been added in GCC 4.8. The option to enable this feature is `-fsanitize=thread`.

#### Compiling Extremely Large Functions

Many scalability bottlenecks have been removed from GCC optimization passes. As a consequence, it is now possible to compile extremely large functions with smaller memory consumption in less time.

#### New -Og Optimization Level

A new general optimization level, `-Og`, has been introduced. This optimization level addresses the need for fast compilation and a superior debugging experience while providing a reasonable level of runtime performance. Overall, the development experience should be better than the default optimization level `-O0`.

#### Caret Diagnostic Messages

The diagnostic messages of GCC, which display a line of source code, now also show a caret that indicates the column where the problem was detected. For example:

```
fred.cc:4:15: fatal error: foo: No such file or directory
#include <foo>
^
compilation terminated.
```

#### New -fira-hoist-pressure Option

A new command line option, `-fira-hoist-pressure`, has been added. This option uses the register allocator to help decide when it is worthwhile to move expressions out of loops. It can reduce the size of
the compiler code, but it slows down the compiler. This option is enabled by default at -O0.

New -fopt-info Option
A new command line option, -fopt-info, has been added. This option controls printing information about the effects of particular optimization passes, and takes the following form:

```
-fopt-info[-info][=file_name]
```

The info part of the option controls what is printed. Replace it with optimized to print information when optimization takes place, missed to print information when optimization does not take place, note to print more verbose information, or optall to print everything.

Replace file_name with the name of the file in which you want the information to be written. If you omit this part of the option, GCC writes the information to the standard error output stream.

For example, to display a list of optimizations that were enabled by the -O2 option but had no effect when compiling a file named foo.c, type:

```
gcc -O2 -fopt-info-missed foo.c
```

New -floop-nest-optimize Option
A new command line option, -floop-nest-optimize, has been added. This option enables an experimental ISL-based loop nest optimizer, a generic loop nest optimizer that is based on the Pluto optimization algorithms and that calculates a loop structure optimized for data-locality and parallelism.

For more information about this optimizer, see [http://pluto-compiler.sourceforge.net](http://pluto-compiler.sourceforge.net).

Hot and Cold Attributes on Labels
The hot and cold function attributes can now also be applied to labels. Hot labels tell the compiler that the execution path following the label is more likely than any other execution path, and cold labels convey the opposite meaning. These attributes can be used in cases where __builtin_expect cannot be used, for instance with a computed goto or asm goto.

A.2.1.3. Debugging Enhancements

DWARF4
DWARF4 is now used as the default debugging data format when generating debugging information. To get the maximum benefit from this new debugging representation, use the latest version of Valgrind, elfutils, and GDB included in this release.

New -gsplit-dwarf Option
A new command line option, -gsplit-dwarf, has been added. This option tells the compiler driver to separate as much DWARF debugging information as possible into a separate output file with the .dwo file extension, and allows the build system to avoid linking files with debugging information.

In order to be useful, this option requires a debugger capable of reading .dwo files, such as the version of GDB included in Red Hat Developer Toolset 2.0.
Note

elfutils, SystemTap, and Valgrind do not support the .dwo files.

A.2.1.4. C++ Changes

Experimental C++ Features from an Upcoming Standard
g++ now supports a new command line option, -std=c++1y. This option can be used for experimentation with features proposed for the next revision of the standard that is expected around 2014. Currently, the only difference from -std=c++11 is support for return type deduction in normal functions as proposed in N3386.

New thread_local Keyword
g++ now implements the C++11 thread_local keyword. In comparison with the GNU __thread keyword, thread_local allows dynamic initialization and destruction semantics. See the next item for dynamic initialization issues.

Dynamic Initialization of Thread-local Variables
The C++11 and OpenMP standards allow thread-local and thread-private variables to have dynamic (that is, runtime) initialization. To support this, any use of such a variable goes through a wrapper function that performs necessary initialization.

When the use and definition of the variable are in the same translation unit, this overhead can be optimized away, but when the use is in a different translation unit, there is significant overhead even if the variable does not actually need dynamic initialization. If the programmer can be sure that no use of the variable in a non-defining translation unit needs to trigger dynamic initialization (either because the variable is statically initialized, or a use of the variable in the defining translation unit will be executed before any uses in another translation unit), they can avoid this overhead by using the new -fno-extern-tls-init option.

By default, g++ uses the -fextern-tls-init option.

C++11 Attribute Syntax
g++ now implements the C++11 attribute syntax, for example:

```cpp
[[noreturn]] void f();
```

C++11 Alignment Specifier
g++ now implements the C++11 alignment specifier, for example:

```cpp
alignas(double) int i;
```

A.2.1.5. Fortran Changes

A.2.1.5.1. Caveats
The version of module files (the .mod files) has been incremented. Fortran modules compiled by earlier GCC versions have to be recompiled when they are used by files compiled with GCC 4.8, as this version of GCC is not able to read .mod files created by earlier versions; attempting to do so fails with an error.
message.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>The ABI of the produced assembler data itself has not changed; object files and libraries are fully compatible with older versions except as noted in Section A.2.1.5.2, “ABI Compatibility”.</td>
</tr>
</tbody>
</table>

A.2.1.5.2. ABI Compatibility

Some internal names used in the assembler or object file have changed for symbols declared in the specification part of a module. If an affected module — or a file using it via use association — is recompiled, the module and all files which directly use such symbols have to be recompiled as well. This change only affects the following kind of module symbols:

- **Procedure pointers.** Note that C-interoperable function pointers (**type(c_funptr)**) are not affected, nor are procedure-pointer components.
- **Deferred-length character strings.**

A.2.1.5.3. Other Changes

**BACKTRACE Intrinsic**

A new intrinsic subroutine, **BACKTRACE**, has been added. This subroutine shows a backtrace at an arbitrary place in user code, program execution continues normally afterwards.

**Floating Point Numbers with “q” as Exponential**

Reading floating point numbers that use **q** for the exponential (such as **4.0q0** is now supported as a vendor extension for better compatibility with old data files. It is strongly recommended to use the equivalent but standard conforming **e** (such as **4.0e0**) for I/O.

For Fortran source code, consider replacing the **q** in floating-point literals by a kind parameter (such as **4.0e0_qp** with a suitable **qp**). Note that — in Fortran source code — replacing **q** with a simple **e** is not equivalent.

**GFORTRAN_TMPDIR Environment Variable**

The **GFORTRAN_TMPDIR** environment variable for specifying a non-default directory for files opened with **STATUS="SCRATCH"**, is not used anymore. Instead, **gfortran** checks the POSIX/GNU standard **TMPDIR** environment variable and if **TMPDIR** is not defined, **gfortran** falls back to other methods to determine the directory for temporary files as documented in the user manual.

**Fortran 2003**

Support for unlimited polymorphic variables (**CLASS(*)**) has been added. Non-constant character lengths are not yet supported.

**TS 29113**

Assumed types (**TYPE(*)**) are now supported.

Experimental support for assumed-rank arrays (**dimension(..)**) has been added. Note that at the moment, the **gfortran** array descriptor is used, which is different from the array descriptor defined in **TS 29113**. For more information, see the header file of **gfortran** or use the Chasm language interoperability tools.
A.2.1.6. x86-specific Improvements

New Instructions
GCC 4.8 has added support for the Intel FXSR, XSAVE, and XSAVEOPT instructions. Corresponding intrinsics and built-in functions can now be enabled by using the -mfxsr, -mxsave, and -mxsaveopt command line options respectively.

In addition, support for the RDSEED, ADCX, ADOX, and PREFETCHW instructions has been added and can be enabled by using the -mrdseed, -madx, and -mprfchw command line options.

New Built-in Functions to Detect Run-time CPU Type and ISA
A new built-in function, __builtin_cpu_is(), has been added to detect if the run-time CPU is of a particular type. This function accepts one string literal argument with the CPU name, and returns a positive integer on a match and zero otherwise. For example, __builtin_cpu_is("westmere") returns a positive integer if the run-time CPU is an Intel Core i7 Westmere processor. For a complete list of valid CPU names, see the user manual.

A new built-in function, __builtin_cpu_supports(), has been added to detect if the run-time CPU supports a particular ISA feature. This function accepts one string literal argument with the ISA feature, and returns a positive integer on a match and zero otherwise. For example, __builtin_cpu_supports("ssse3") returns a positive integer if the run-time CPU supports SSSE3 instructions. For a complete list of valid ISA names, see the user manual.

Important
If these built-in functions are called before any static constructors are invoked, such as IFUNC initialization, then the CPU detection initialization must be explicitly run using this newly provided built-in function, __builtin_cpu_init(). The initialization needs to be done only once. For example, the following is sample invocation inside an IFUNC initializer:

```
static void (*some_ifunc_resolver(void))(void)
{
    __builtin_cpu_init();
    if (__builtin_cpu_is("amdfam10h") ... 
    if (__builtin_cpu_supports("popcnt") ... 
}
```

Function Multiversioning
Function multiversioning allows the programmer to specify multiple versions of the same function, each of which is specialized for a particular variant of a given target. At runtime, the appropriate version is automatically executed depending upon the target where the execution takes place. For example, consider the following code fragment:

```
__attribute__((target("default"))) int foo () { return 0; }
__attribute__((target("sse4.2"))) int foo () { return 1; }
__attribute__((target("arch=atom"))) int foo () { return 2; }
```

When the function foo() is executed, the result returned depends upon the architecture where the program runs, not the architecture where the program was compiled. See the GCC Wiki for more details.
New RTM and HLE Intrinsics
Support for the Intel RTM and HLE intrinsics, built-in functions, and code generation has been added and can be enabled by using the `-mrtm` and `-mhle` command line options. This is done via intrinsics for Restricted Transactional Memory (RTM) and extensions to the memory model for Hardware Lock Elision (HLE).

For HLE, two new flags can be used to mark a lock as using hardware elision:

```c
__ATOMIC_HLE_ACQUIRE
   Starts lock elision on a lock variable. The memory model in use must be __ATOMIC_ACQUIRE or stronger.

__ATOMIC_HLE_RELEASE
   Ends lock elision on a lock variable. The memory model must be __ATOMIC_RELEASE or stronger.
```

For example, consider the following code fragment:

```c
while (__atomic_exchange_n (& lockvar, 1, __ATOMIC_ACQUIRE | __ATOMIC_HLE_ACQUIRE))
    _mm_pause ();
// work with the acquired lock
__atomic_clear (& lockvar, __ATOMIC_RELEASE | __ATOMIC_HLE_RELEASE);
```

The new intrinsics that support Restricted Transactional Memory are:

```c
unsigned _xbegin (void)
   Attempts to start a transaction. If it succeeds, this function returns _XBEGIN_STARTED, otherwise it returns a status value indicating why the transaction could not be started.

void _xend (void)
   Commits the current transaction. When no transaction is active, this function causes a fault. All memory side effects of the transactions become visible to other threads in an atomic manner.

int _xtest (void)
   Returns a non-zero value if a transaction is currently active, or zero if it is not.

void _xabort (unsigned char status)
   Aborts the current transaction. When no transaction is active, this is a no-op. The parameter status is included in the return value of any _xbegin() call that is aborted by this function.
```

The following example illustrates the use of these intrinsics:
Transactions Using Transactional Synchronization Extensions
Transactions in the transactional memory feature (the `-fgnu-tm` option) of GCC can now be run using Transactional Synchronization Extensions (TSX) if available on x86 hardware.

Support for AMD Family 15h Processors
The x86 backend of GCC now supports CPUs based on AMD Family 15h cores with the 64-bit x86 instruction set support. This can be enabled by using the `-march=bdver3` option.

Support for AMD Family 16h Processors
The x86 backend of GCC now supports CPUs based on AMD Family 16h cores with the 64-bit x86 instruction set support. This can be enabled by using the `-march=btver2` option.

A.2.2. Changes Since Red Hat Enterprise Linux 6.4 and 5.9
The following features have been added since the release of GCC included in Red Hat Enterprise Linux 6.4 and 5.9:

A.2.2.1. Status and Features

A.2.2.1.1. C++11
GCC 4.7 and later provides experimental support for building applications compliant with C++11 using the `-std=c++11` or `-std=gnu++11` command line options. However, there is no guarantee for compatibility between C++11 code compiled by different versions of the compiler. Refer to Section A.2.2.3.1, “C++ ABI”, for details.

The C++ runtime library, `libstdc++`, supports a majority of the C++11 features. However, there is no or only partial support for some features such as certain properties on type traits or regular expressions. For details, refer to the `libstdc++ documentation`, which also lists implementation-defined behavior.

Support for C++11 `exception_ptr` and `future` requires changes to the exception handling runtime in the system `libstdc++` package. These changes will be distributed through the normal Z-stream channel. Application of all Red Hat Enterprise Linux errata may be required to see correct runtime functionality when using these features.

A.2.2.1.2. C11
GCC 4.7 and later provides experimental support for some of the features from the C11 revision of the ISO C standard, and in addition to the previous (now deprecated) `-std=c1x` and `-std=gnu1x` command line options, gcc now accepts `-std=c11` and `-std=gnu11`. Note that since this support is experimental, it may change incompatibly in future releases.

Examples for features that are supported are Unicode strings (including the predefined macros
A.2.2.1.3. Parallelism and Concurrency

GCC 4.7 and later provides improved support for programming parallel applications:

1. The GCC compilers support the OpenMP API specification for parallel programming, version 3.1. Refer to the OpenMP website for more information about this specification.

2. The C++11 and C11 standards provide programming abstractions for multi-threaded programs. The respective standard libraries include programming abstractions for threads and thread-related features such as locks, condition variables, or futures. These new versions of the standard also define a memory model that precisely specifies the runtime behavior of a multi-threaded program, such as the guarantees provided by compilers and the constraints programmers have to pay attention to when writing multi-threaded programs.

   Note that support for the memory model is still experimental (see below for details). For more information about the status of support for C++11 and C11, refer to Section A.2.2.1.1, “C++11” and Section A.2.2.1.2, “C11” respectively.

The rest of this section describes two new GCC features in more detail. Both these features make it easier for programmers to handle concurrency (such as when multiple threads do not run truly in parallel but instead have to synchronize concurrent access to shared state), and both provide atomicity for access to memory but differ in their scope, applicability, and complexity of runtime support.

C++11 Types and GCC Built-ins for Atomic Memory Access

C++11 has support for atomic types. Access to memory locations of this type is atomic, and appears as one indivisible access even when other threads access the same memory location concurrently. The atomicity is limited to a single read or write access or one of the other atomic operations supported by such types (for example, two subsequent operations executed on a variable of atomic type are each atomic separately, but do not form one joint atomic operation).

An atomic type is declared as `atomic<T>`, where T is the non-atomic base type and must be trivially copyable (for example, `atomic<int>` is an atomic integer). GCC does not yet support any base type T, but only those that can be accessed atomically with the atomic instructions offered by the target architecture. This is not a significant limitation in practice, given that atomics are primarily designed to expose hardware primitives in an architecture-independent fashion; pointers and integrals that are not larger than a machine word on the target are supported as base types. Using base types that are not yet supported results in link-time errors.

The code generated for operations on atomic types, including the memory orders, implements the semantics specified in the C++11 standard. However, support for the C++11 memory model is still experimental, and for example GCC might not always preserve data-race freedom when optimizing code.

GCC also supports new built-ins for atomic memory accesses, which follow the design of the memory model and new atomic operations. The former set of synchronization built-ins (that is, those prefixed with __sync) are still supported.

Transactional Memory

Transactional Memory (TM) allows programs to declare that a piece of code is supposed to execute as a transaction, that is, virtually atomically and in isolation from other transactions. GCC's transactional memory runtime library, libitm, then ensures this atomicity guarantee when executing the compiled program. Compared to atomic memory accesses, it is a higher-level programming abstraction, because it is not limited to single memory locations, does not require special data types for the data it modifies, and because transactions can contain arbitrary code and be nested within other transactions (with some
restrictions explained subsequently).

GCC implements transactions as specified in the Draft Specification for Transactional Language Constructs for C++, version 1.1. This draft does not yet specify the language constructs for C, but GCC already supports a C-compatible subset of the constructs when compiling C source code.

The main language constructs are transaction statements and expressions, and are declared by the __transaction_atomic or __transaction_relaxed keywords followed by a compound statement or expression, respectively. The following example illustrates how to increment a global variable y if another variable x has a value less than 10:

```
__transaction_atomic { if (x < 10) y++; }
```

This happens atomically even in a multi-threaded execution of the program. In particular, even though the transaction can load x and y and store to y, all these memory accesses are virtually executed as one indivisible step.

Note that in line with the C++11 memory model, programs that use transactions must be free of data races. Transactions are guaranteed to be virtually executed serially in a global total order that is determined by the transactional memory implementation and that is consistent with and contributes to the happens-before order enforced by the rest of the program (that is, transaction semantics are specified based on the C++11 memory model, see the draft specification linked above). Nonetheless, if a program is not data-race-free, then it has undefined behavior. For example, a thread can first initialize some data and then make it publicly accessible by code like this:

```
init(data);
__transaction_atomic { data_public = true;} // data_public is initially false
```

Another thread can then safely use the data, for instance:

```
__transaction_atomic { if (data_public) use(data); }
```

However, the following code has a data race and thus results in undefined behavior:

```
__transaction_atomic { temp = copy(data); if (data_public) use(temp); }
```

Here, copy(data) races with init(data) in the initializing thread, because this can be executed even if data_public is not true. Another example for data races is one thread accessing a variable x transactionally and another thread accessing it nontransactionally at potentially the same time. Note that the data can be safely reclaimed using code like this (assuming only one thread ever does this):

```
__transaction_atomic { data_public = false; }
destruct(data);
```

Here, destruct() does not race with potential concurrent uses of the data because after the transaction finishes, it is guaranteed that data_public is false and thus data is private. See the specification and the C++11 memory model for more background information about this.

Note that even if transactions are required to virtually execute in a total order, this does not mean that they execute mutually exclusive in time. Transactional memory implementations attempt to run transactions as much in parallel as possible to provide scalable performance.

There are two variants of transactions: atomic transactions (__transaction_atomic) and relaxed transactions (__transaction_relaxed). The former guarantee atomicity with regard to all other code,
but allow only code that is known to not include nontransactional kinds of synchronization, such as atomic or volatile memory access. In contrast, relaxed transactions allow all code (for example calls to I/O functions), but only provide atomicity with regard to other transactions. Therefore, atomic transactions can be nested within other atomic and relaxed transactions, but relaxed transactions can only be nested within other relaxed transactions. Furthermore, relaxed transactions are likely to be executed with less performance, but this depends on the implementation and available hardware.

GCC verifies these restrictions statically at compile time (for example, the requirements on code allowed to be called from within atomic transactions). This has implications for when transactions call functions that are defined within other compilation unit (source file) or within libraries. To enable such cross-compilation-unit calls for transactional code, the respective functions must be marked to contain code that is safe to use from within atomic transactions. Programmers can do so by adding the `transaction_safe` function attribute to the declarations of these functions and by including this declaration when defining the function. In turn, GCC then verifies that the code in these functions is safe for atomic transactions and generates code accordingly. If the programmer does not follow these constraints and/or steps, compile-time or link-time errors occur. Note that within a compilation unit, GCC detects automatically whether a function is safe for use within transactions, and the attributes therefore typically do not need to be added. See the draft specification linked above for further details.

GCC's transactional memory support is designed in such a way that it does not decrease the performance of programs that do not use transactions, nor the performance of nontransactional code, except due to the normal kinds of interference by concurrent threads that use the same resources such as the CPU.

Transactional memory support in GCC and `libitm` is still experimental, and both the ABI and API could change in the future if this is required due to the evolution of the specification of the language constructs, or due to implementation requirements. Note that when executing applications built with the `-fgnu-tm` command line option, it is currently a prerequisite to also have the appropriate version of the `libitm.so.1` shared library installed.

### A.2.2.1.4. Architecture-specific Options

Red Hat Developer Toolset 2.0 is only available for Red Hat Enterprise Linux 5 and 6, both for the 32-bit and 64-bit Intel and AMD architectures. Consequently, the options described below are only relevant to these architectures.

Optimization for several processors is now available through the command line options described in Table A.1, "Processor Optimization Options".
### Table A.1. Processor Optimization Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-march=core2 and -mtune=core2</td>
<td>Optimization for Intel Core 2 processors.</td>
</tr>
<tr>
<td>-march=corei7 and -mtune=corei7</td>
<td>Optimization for Intel Core i3, i5, and i7 processors.</td>
</tr>
<tr>
<td>-march=corei7-avx and -mtune=corei7-avx</td>
<td>Optimization for Intel Core i3, i5, and i7 processors with AVX.</td>
</tr>
<tr>
<td>-march=core-avx-i</td>
<td>Optimization for the Intel processor code-named Ivy Bridge with RDRND, FSGSBASE, and F16C.</td>

</tbody>
</table>
When using the x87 floating-point unit, GCC now generates code that conforms to ISO C99 in terms of handling of floating-point excess precision. This can be enabled by -fexcess-precision=standard and disabled by -fexcess-precision=fast. This feature is enabled by default when using standards conformance options such as -std=c99.

Vectors of type vector long long or vector long are passed and returned using the same method as other vectors with the VSX instruction set. Previously GCC did not adhere to the ABI for 128-bit vectors with 64-bit integer base types (see GCC PR 48857).

The -mrecip command line option has been added, which indicates whether the reciprocal and reciprocal square root instructions should be used.

The -mveclibabi=mass command line option has been added. This can be used to enable the compiler to auto-vectorize mathematical functions using the Mathematical Acceleration Subsystem library.

The -msingle-pic-base command line option has been added, which instructs the compiler to avoid loading the PIC base register in function prologues. The PIC base register must be initialized by the runtime system.

The -mblock-move-inline-limit command line option has been added, which enables the user to control the maximum size of inlined memcpy calls and similar.

### A.2.2.1.5. Link-time Optimization

Link-time optimization (LTO) is a compilation technique in which GCC generates an internal representation of each compiled input file in addition to the native code, and writes both to the output object file. Subsequently, when several object files are linked together, GCC uses the internal representations of the compiled code to optimize inter-procedurally across all the compilation units. This can potentially improve the performance of the generated code (for example, functions defined in one file can potentially be inlined when called in another file).

To enable LTO, the -flto option needs to be specified at both compile time and link time. For further details, including interoperability with linkers and parallel execution of LTO, refer to the documentation for -flto in the [GCC 4.7.0 Manual](https://gcc.gnu.org/onlinedocs/gcc/). Also note that the internal representation is not a stable interface, so LTO will only apply to code generated by the same version of GCC.

**Note**

Use of Link-time Optimization with debug generation is not yet supported in gcc 4.7 and 4.8 and so use of the -flto and the -g options together is unsupported in Red Hat Developer Toolset.

### A.2.2.1.6. Miscellaneous

-Ofast is now supported as a general optimization level. It operates similar to -O3, adds options that can yield better-optimized code, but in turn might invalidate standards compliance (for example, -ffast-math is enabled by -Ofast).

GCC can now inform users about cases in which code generation might be improved by adding attributes such as `const`, `pure`, and `noret`urn to functions declared in header files. Use the `-Wsuggest-attribute=[const|pure|noret`urn] command line option to enable this.

Assembler code can now make use of a goto feature that allows for jumps to labels in C code.
A.2.2.2. Language Compatibility

In this section, we describe the compatibility between the Red Hat Developer Toolset compilers and the Red Hat Enterprise Linux system compilers at the programming-language level (for example, differences in the implementation of language standards such as C99, or changes to the warnings generated by -Wall).

Some of the changes are a result of bug fixing, and some old behaviors have been intentionally changed in order to support new standards, or relaxed in standards-conforming ways to facilitate compilation or runtime performance. Some of these changes are not visible to the naked eye and will not cause problems when updating from older versions. However, some of these changes are visible, and can cause grief to users porting to Red Hat Developer Toolset's version of GCC. The following text attempts to identify major issues and suggests solutions.

A.2.2.2.1. C

Constant expressions are now handled by GCC in a way that conforms to C90 and C99. For code expressions that can be transformed into constants by the compiler but are in fact not constant expressions as defined by ISO C, this may cause warnings or errors.

Ill-formed redeclarations of library functions are no longer accepted by the compiler. In particular, a function with a signature similar to the built-in declaration of a library function (for example, abort() or memcpy()) must be declared with extern "C" to be considered as a redeclaration, otherwise it is ill-formed.

Duplicate Member

Consider the following struct declaration:

```c
struct A { int *a; union { struct { int *a; }; }; }
```

Previously, this declaration used to be diagnosed just by the C++ compiler, now it is also diagnosed by the C compiler. Because of the anonymous unions and structs, there is ambiguity about what .a actually refers to and one of the fields therefore needs to be renamed.

A.2.2.2.2. C++

Header Dependency Changes

<iostream>, <string>, and other STL headers that previously included <unistd.h> as an implementation detail (to get some feature macros for gthr*.h purposes) no longer do so, because it was a C++ standard violation. This can result in diagnostic output similar to the following:

```plaintext
error: ‘truncate’ was not declared in this scope
error: ‘sleep’ was not declared in this scope
error: ‘pipe’ was not declared in this scope
error: there are no arguments to 'offsetof' that depend on a template parameter, so a declaration of 'offsetof' must be available
```

To fix this, add the following line early in the source or header files that need it:

```c
#include <unistd.h>
```

Many of the standard C++ library include files have been edited to no longer include <cstdlib> to get namespace-std-scoped versions of size_t and ptrdiff_t. As such, C++ programs that used the
macros **NULL** or **offsetof** without including `<cstddef>` will no longer compile. The diagnostic produced is similar to the following:

```
error: 'ptrdiff_t' does not name a type
error: 'size_t' has not been declared
error: 'NULL' was not declared in this scope
error: there are no arguments to 'offsetof' that depend on a template parameter, so a declaration of 'offsetof' must be available
```

To fix this issue, add the following line:

```
#include <cstddef>
```

**Name Lookup Changes**

G++ no longer performs an extra unqualified lookup that it incorrectly performed in the past. Instead, it implements the two-phase lookup rules correctly, and an unqualified name used in a template must have an appropriate declaration that:

1. is either in scope at the point of the template's definition, or
2. can be found by argument-dependent lookup at the point of instantiation.

Code that incorrectly depends on a second unqualified lookup at the point of instantiation (such as finding functions declared after the template or in dependent bases) will result in compile-time errors.

In some cases, the diagnostics provided by G++ include hints how to fix the bugs. Consider the following code:

```cpp
template<typename T>
int t(T i)
{
    return f(i);
}

int f(int i)
{
    return i;
}

int main()
{
    return t(1);
}
```

The following diagnostics output will be produced:

```
In instantiation of 'int t(T) [with T = int]'
required from here
error: 'f' was not declared in this scope, and no declarations were found by argument-dependent lookup at the point of instantiation [-fpermissive]
note: 'int f(int)' declared here, later in the translation unit
```

To correct the error in this example, move the declaration of function `f()` before the definition of template function `t()`. The `-fpermissive` compiler flag turns compile-time errors into warnings and can be used as a temporary workaround.
Uninitialized const

Consider the following declaration:

```cpp
struct A { int a; A ();
struct B : public A { 
const B b;
```

An attempt to compile this code now fails with the following error:

```
error: uninitialized const ‘b’ [-fpermissive]
note: ‘const struct B’ has no user-provided default constructor
```

This happens, because `B` does not have a user-provided default constructor. Either an initializer needs to be provided, or the default constructor needs to be added.

Visibility of Template Instantiations

The ELF symbol visibility of a template instantiation is now properly constrained by the visibility of its template arguments. For instance, users that instantiate standard library components like `std::vector` with hidden user defined types such as `struct my_hidden_struct` can now expect hidden visibility for `std::vector<my_hidden_struct>` symbols. As a result, users that compile with the `-fvisibility=hidden` command line option should be aware of the visibility of types included from the library headers used. If the header does not explicitly control symbol visibility, types from those headers will be hidden, along with instantiations that use those types. For instance, consider the following code:

```cpp
#include <vector>  // template std::vector has default visibility
#include <ctime>  // struct tm has hidden visibility
template class std::vector<tm>; // instantiation has hidden visibility
```

One approach to adjusting the visibility of a library header `<foo.h>` is to create a forwarding header on the `-I` include path consisting of the following:

```cpp
#pragma GCC visibility push(default)
#include_next <foo.h>
#pragma GCC visibility push
```

User-defined Literal Support

When compiling C++ with the `-std={c++11,c++0x,gnu++11,gnu++0x}` command line option, GCC 4.7.0 and later, unlike older versions, supports user-defined literals, which are incompatible with some valid ISO C++03 code. In particular, white space is now needed after a string literal before something that could be a valid user defined literal. Consider the following code:

```cpp
const char *p = "foobar"__TIME__;
```

In C++03, the `__TIME__` macro expands to some string literal and is concatenated with the other one. In C++11, `__TIME__` is not expanded and instead, operator `"" __TIME__` is being looked up, which results in a warning like:

```
error: unable to find string literal operator ‘operator"" __TIME__’
```

This applies to any string literal followed without white space by some macro. To fix this, add some white space between the string literal and the macro name.
**Taking the Address of Temporary**

Consider the following code:

```cpp
struct S { S (); int i; };  
void bar (S *);  
void foo () { bar (&S()); }
```

Previously, an attempt to compile this code produced a warning message, now it fails with an error. This can be fixed by adding a variable and passing the address of this variable instead of the temporary. The `-fpermissive` compiler flag turns compile-time errors into warnings and can be used as a temporary workaround.

**Miscellaneous**

G++ now sets the predefined macro `__cplusplus` to the correct value: `199711L` for C++98/03, and `201103L` for C++11. G++ now properly re-uses stack space allocated for temporary objects when their lifetime ends, which can significantly lower stack consumption for some C++ functions. As a result of this, some code with undefined behavior will now break.

When an extern declaration within a function does not match a declaration in the enclosing context, G++ now properly declares the name within the namespace of the function rather than the namespace which was open just before the function definition.

G++ now implements the proposed resolution of the C++ standard's core issue 253. Default initialization is allowed if it initializes all subobjects, and code that fails to compile can be fixed by providing an initializer such as:

```cpp
struct A { A(); };  
struct B : A { int i; };  
const B b = B();
```

Access control is now applied to `typedef` names used in a template, which may cause G++ to reject some ill-formed code that was accepted by earlier releases. The `-fno-access-control` option can be used as a temporary workaround until the code is corrected.

G++ now implements the C++ standard's core issue 176. Previously, G++ did not support using the injected-class-name of a template base class as a type name, and lookup of the name found the declaration of the template in the enclosing scope. Now lookup of the name finds the injected-class-name, which can be used either as a type or as a template, depending on whether or not the name is followed by a template argument list. As a result of this change, some code that was previously accepted may be ill-formed, because:

1. the injected-class-name is not accessible because it is from a private base, or
2. the injected-class-name cannot be used as an argument for a template parameter.

In either of these cases, the code can be fixed by adding a nested-name-specifier to explicitly name the template. The first can be worked around with `-fno-access-control`, the second is only rejected with `-pedantic`.

**A.2.2.2.3. C/C++ Warnings**

GCC 4.7.0 and later adds a number of new warnings that are either enabled by default, or by using the `-Wall` option. Although these warnings do not result in a compilation failure on their own, often `-Wall` is
used in conjunction with `-Werror`, causing these warnings to act like errors. This section provides a list of these new or newly enabled warnings. Unless noted otherwise, these warnings apply to both C and C++.

The behavior of the `-Wall` command line option has changed and now includes the new warning flags `-Wunused-but-set-variable` and, with `-Wall -Wextra`, `-Wunused-but-set-parameter`. This may result in new warnings in code that compiled cleanly with previous versions of GCC. For example, consider the following code:

```c
void fn (void)
{
    int foo;
    foo = bar (); /* foo is never used. */
}
```

The following diagnostic output will be produced:

```
warning: variable "foo" set but not used [-Wunused-but-set-variable]
```

To fix this issue, first see if the unused variable or parameter can be removed without changing the result or logic of the surrounding code. If not, annotate it with `__attribute__((__unused__))`. As a workaround, you can use the `-Wno-error=unused-but-set-variable` or `-Wno-error=unused-but-set-parameter` command line option.

The `-Wenum-compare` option causes GCC to report a warning when values of different enum types are being compared. Previously, this option only worked for C++ programs, but now it works for C as well. This warning is enabled by `-Wall` and may be avoided by using a type cast.

Casting integers to larger pointer types now causes GCC to display a warning by default. To disable these warnings, use the `-Wno-int-to-pointer-cast` option, which is available for both C and C++.

Conversions between NULL and non-pointer types now cause GCC to report a warning by default. Previously, these warnings were only displayed when explicitly using `-Wconversion`. To disable these warnings, use the new `-Wno-conversion-null` command line option.

GCC can now warn when a class that has virtual functions and a non-virtual destructor is destroyed by using `delete`. This is unsafe to do because the pointer might refer to a base class that does not have a virtual destructor. The warning is enabled by `-Wall` and by a new command line option, `-Wdelete-non-virtual-dtor`.

New `-Wc++11-compat` and `-Wc++0x-compat` options are now available. These options cause GCC to display a warning about C++ constructs whose meaning differs between ISO C++ 1998 and ISO C++ 2011 (such as identifiers in ISO C++ 1998 that are keywords in ISO C++ 2011). This warning is enabled by `-Wall` and enables the `-Wnarrowing` option.

A.2.2.2.4. Fortran

A.2.2.2.4.1. New Features

- A new compile flag `-fstack-arrays` has been added. This flag causes all local arrays to be put on stack memory, which can significantly improve the performance of some programs. Note that programs that use very large local arrays may require you to extend your runtime limits for stack memory.
- Compile time has been significantly improved. For example, the improvement may be noticeable when
working with programs that use large array constructors.

To improve code generation and diagnostics, the `-fwhole-file` compile flag is now enabled by default, and can be used with a newly supported `-fwhole-program` flag. To disable it, use the deprecated `-fno-whole-file` flag.

A new command line option `-M` is now supported. Similarly to `gcc`, this option allows you to generate Makefile dependencies. Note that the `-cpp` option may be required as well.

The `-finit-real=` command line option now supports `snan` as a valid value. This allows you to initialize REAL and COMPLEX variables with a signaling NaN (not a number), and requires you to enable trapping (for example, by using the `-ffpe-trap=` command line option). Note that compile-time optimizations may turn a signaling NaN into a quiet NaN.

A new command line option `-fcheck=` has been added. This option accepts the following arguments:

- The `-fcheck=bounds` option is equivalent to the `-fbounds-check` command line option.
- The `-fcheck=array-temps` option is equivalent to the `-fcheck-array-temporaries` command line option.
- The `-fcheck=do` option checks for invalid modification of loop iteration variables.
- The `-fcheck=recursive` option checks for recursive calls to subroutines or functions that are not marked as recursive.
- The `-fcheck=pointer` option performs pointer association checks in calls, but does not handle undefined pointers nor pointers in expressions.
- The `-fcheck=all` option enables all of the above options.

A new command line option `-fno-protect-parens` has been added. This option allows the compiler to reorder REAL and COMPLEX expressions with no regard to parentheses.

When OpenMP’s `WORKSHARE` is used, array assignments and `WHERE` will now be run in parallel.

More Fortran 2003 and Fortran 2008 mathematical functions can now be used as initialization expressions.

The GCC$ compiler directive now enables support for some extended attributes such as `STDCALL`.

### A.2.2.2.4.2. Compatibility Changes

- The `-Ofast` command line option now automatically enables the `-fno-protect-parens` and `-fstack-arrays` flags.
- Front-end optimizations can now be disabled by the `-fno-frontend-optimize` option, and selected by the `-ffrontend-optimize` option. The former is essentially only desirable if invalid Fortran source code needs to be compiled (for example, when functions—as compared to subroutines—have side-effects) or to work around compiler bugs.
- The `GFORTRAN_USE_STDERR` environment variable has been removed, and GNU Fortran now always prints error messages to standard error.
- The `-fdump-core` command line option and the `GFORTRAN_ERROR_DUMPCORE` environment variable have been removed. When encountering a serious error, GNU Fortran now always aborts the execution of the program.
- The `-fbacktrace` command line option is now enabled by default. When a fatal error occurs, GNU Fortran now attempts to print a backtrace to standard error before aborting the execution of the program. To disable this behavior, use the `-fno-backtrace` option.
- GNU Fortran no longer supports the use of the `-M` command line option to generate Makefile dependencies for the module path. To perform this operation, use the `-J` option instead.
- To significantly reduce the number of warnings, the `-Wconversion` command line option now only...
displays warnings when a conversion leads to information loss, and a new command line option `-Wconversion-extra` has been added to display warnings about other conversions. The `-Wconversion` option is now enabled with `-Wall`.

- A new command line option `-Wunused-dummy-argument` has been added. This option can be used to display warnings about unused dummy arguments, and is now enabled with `-Wall`. Note that the `-Wunused-variable` option previously also warned about unused dummy arguments.

- The `COMMON` default padding has been changed. Previously, the padding was added before a variable. Now it is added after a variable to increase the compatibility with other vendors, as well as to help to obtain the correct output in some cases. Note that this behavior is in contrast with the behavior of the `-falign-commons` option.

- GNU Fortran no longer links against the `libgfortranbegin` library. The `MAIN__` assembler symbol is the actual Fortran main program and is invoked by the `main` function, which is now generated and put in the same object file as `MAIN__`. Note that the `libgfortranbegin` library is still present for backward compatibility.

A.2.2.2.4.3. Fortran 2003 Features

- Improved but still experimental support for polymorphism between libraries and programs and for complicated inheritance patterns.

- Generic interface names which have the same name as derived types are now supported, which allows the creation of constructor functions. Note that Fortran does not support static constructor functions; only default initialization or an explicit structure-constructor initialization are available.

- Automatic (re)allocation: In intrinsic assignments to allocatable variables, the left-hand side will be automatically allocated (if unallocated) or reallocated (if the shape or type parameter is different). To avoid the small performance penalty, you can use `a(:) = ...` instead of `a = ...` for arrays and character strings — or disable the feature using `-std=f95` or `-fno-realloc-lhs`.

- Experimental support of the `ASSOCIATE` construct has been added.

- In pointer assignments it is now possible to specify the lower bounds of the pointer and, for a rank-1 or a simply contiguous data-target, to remap the bounds.

- Deferred type parameter: For scalar allocatable and pointer variables the character length can now be deferred.

- Namelist variables with allocatable attribute, pointer attribute, and with a non-constant length type parameter are now supported.

- Support has been added for procedure-pointer function results and procedure-pointer components (including `PASS`).

- Support has been added for allocatable scalars (experimental), `DEFERRED` type-bound procedures, and the `ERRMSG=` argument of the `ALLOCATE` and `DEALLOCATE` statements.

- The `ALLOCATE` statement now supports type-specs and the `SOURCE=` argument.

- Rounding (`ROUND=`, `RZ`, `...`) for output is now supported.

- The `INT_FAST{8,16,32,64,128}_T` format for `ISO_C_BINDING` intrinsic module type parameters is now supported.

- `OPERATOR(*)` and `ASSIGNMENT(=)` are now allowed as `GENERIC` type-bound procedures (i.e. as type-bound operators).

A.2.2.2.4.4. Fortran 2003 Compatibility

Extensible derived types with type-bound procedure or procedure pointer with `PASS` attribute now have to use `CLASS` in line with the Fortran 2003 standard; the workaround to use `TYPE` is no longer supported.
A.2.2.4.5. Fortran 2008 Features

A new command line option `-std=f2008ts` has been added. This option enables support for programs that conform to the Fortran 2008 standard and the draft Technical Specification (TS) 29113 on Further Interoperability of Fortran with C. For more information, refer to the Chart of Fortran TS 29113 Features supported by GNU Fortran.

The `DO CONCURRENT` construct is now supported. This construct can be used to specify that individual loop iterations do not have any interdependencies.

Full single-image support except for polymorphic coarrays has been added, and can be enabled by using the `-fcoarray=single` command line option. Additionally, GNU Fortran now provides preliminary support for multiple images via an MPI-based coarray communication library. Note that the library version is not yet usable as remote coarray access is not yet possible.

The `STOP` and `ERROR STOP` statements have been updated to support all constant expressions.

The `CONTIGUOUS` attribute is now supported.

Use of `ALLOCATE` with the `MOLD` argument is now supported.

The `STORAGE_SIZE` intrinsic inquiry function is now supported.

The `NORM2` and `PARITY` intrinsic functions are now supported.

The following bit intrinsics have been added:
- the `POPCNT` and `POPPAR` bit intrinsics for counting the number of 1 bits and returning the parity;
- the `BGE`, `BGT`, `BLE`, and `BLT` bit intrinsics for bitwise comparisons;
- the `DSHIFTL` and `DSHIFTR` bit intrinsics for combined left and right shifts;
- the `MASKL` and `MASKR` bit intrinsics for simple left and right justified masks;
- the `MERGE_BITS` bit intrinsic for a bitwise merge using a mask;
- the `SHIFTA`, `SHIFTL`, and `SHIFTR` bit intrinsics for shift operations;
- the transformational bit intrinsics `IALL`, `IANY`, and `IPARITY`.

The `EXECUTE_COMMAND_LINE` intrinsic subroutine is now supported.

The `IMPURE` attribute for procedures is now supported. This allows the use of `ELEMENTAL` procedures without the restrictions of `PURE`.

Null pointers (including `NULL()`) and unallocated variables can now be used as an actual argument to optional non-pointer, non-allocatable dummy arguments, denoting an absent argument.

Non-pointer variables with the `TARGET` attribute can now be used as an actual argument to `POINTER` dummies with `INTENT(IN)`.

Pointers that include procedure pointers and those in a derived type (pointer components) can now also be initialized by a target instead of only by `NULL`.

The `EXIT` statement (with construct-name) can now be used to leave the `ASSOCIATE`, `BLOCK`, `IF`, `SELECT CASE`, and `SELECT TYPE` constructs in addition to `DO`.

Internal procedures can now be used as actual arguments.

The named constants `INTEGER_KINDS`, `LOGICAL_KINDS`, `REAL_KINDS`, and `CHARACTER_KINDS` of the intrinsic module `ISO_FORTRAN_ENV` have been added. These arrays contain the supported 'kind' values for the respective types.

The `C_SIZEOF` module procedures of the `ISO_C_BINDINGS` intrinsic module and the `COMPILER_VERSION` and `COMPILER_OPTIONS` module procedures of the `ISO_FORTRAN_ENV` intrinsic module have been implemented.

The `OPEN` statement now supports the `NEWUNIT=` option. This option returns a unique file unit and therefore prevents inadvertent use of the same unit in different parts of the program.

Unlimited format items are now supported.
The INT{8,16,32} and REAL{32,64,128} format for ISO_FORTRAN_ENV intrinsic module type parameters are now supported.

It is now possible to use complex arguments with the TAN, SINH, COSH, TANH, ASIN, ACOS, and ATAN functions. Additionally, the new functions ASINH, ACOSH, and ATANH have been added for real and complex arguments, and ATAN(Y,X) now serves as an alias for ATAN2(Y,X).

The BLOCK construct has been implemented.

A.2.2.4.6. Fortran 2008 Compatibility

The implementation of the ASYNCHRONOUS attribute in GCC is now compatible with the candidate draft of TS 29113: Technical Specification on Further Interoperability with C.

A.2.2.4.7. Fortran 77 Compatibility

When the GNU Fortran compiler is issued with the -fno-sign-zero option, the SIGN intrinsic now behaves as if zero were always positive.

A.2.2.3. ABI Compatibility

This section describes compatibility between the Red Hat Developer Toolset compilers and the system compilers at the application binary interface (ABI) level.

A.2.2.3.1. C++ ABI

Because the upstream GCC community development does not guarantee C++11 ABI compatibility across major versions of GCC, the same applies to use of C++11 with Red Hat Developer Toolset. Consequently, using the -std=c++11 option is supported in Red Hat Developer Toolset 2.0 only when all C++ objects compiled with that flag have been built using the same major version of Red Hat Developer Toolset. The mixing of objects, binaries and libraries, built by the Red Hat Enterprise Linux 5 or 6 system toolchain GCC using the -std=c++0x or -std=gnu++0x flags, with those built with the -std=c++11 or -std=gnu++11 flags using the GCC in Red Hat Developer Toolset is explicitly not supported.

As later major versions of Red Hat Developer Toolset may use a later major release of GCC, forward-compatibility of objects, binaries, and libraries built with the -std=c++11 or -std=gnu++11 options cannot be guaranteed, and so is not supported.

The default language standard setting for Red Hat Developer Toolset is C++98. Any C++98-compliant binaries or libraries built in this default mode (or explicitly with -std=c++98) can be freely mixed with binaries and shared libraries built by the Red Hat Enterprise Linux 5 or 6 system toolchain GCC. Red Hat recommends use of this default -std=c++98 mode for production software development.

Important

Use of C++11 features in your application requires careful consideration of the above ABI compatibility information.

Aside from the C++11 ABI, discussed above, the Red Hat Enterprise Linux Application Compatibility Specification is unchanged for Red Hat Developer Toolset. When mixing objects built with Red Hat Developer Toolset with those built with the Red Hat Enterprise Linux v5.x/v6.x toolchain (particularly .o/.a files), the Red Hat Developer Toolset toolchain should be used for any linkage. This ensures any newer library features provided only by Red Hat Developer Toolset are resolved at link-time.

A new standard mangling for SIMD vector types has been added to avoid name clashes on systems with
vectors of varying length. By default the compiler still uses the old mangling, but emits aliases with the
new mangling on targets that support strong aliases. `-wabi` will now display a warning about code that
uses the old mangling.

### A.2.2.3.2. Miscellaneous

GCC now optimizes calls to various standard C string functions such as `strlen()`, `strchr()`,
`strcpy()`, `strcat()` and `stpcpy()` (as well as their respective `_FORTIFY_SOURCE` variants) by
transforming them into custom, faster code. This means that there might be fewer or other calls to those
functions than in the original source code. The optimization is enabled by default at `-O2` or higher
optimization levels. It is disabled when using `-fno-optimize-strlen` or when optimizing for size.

When compiling for 32-bit GNU/Linux and not optimizing for size, `-fomit-frame-pointer` is now
enabled by default. The prior default setting can be chosen by using the `-fno-omit-frame-pointer`
command line option.

Floating-point calculations on x86 targets and in strict C99 mode are now compiled by GCC with a
stricter standard conformance. This might result in those calculations executing significantly slower. It
can be disabled using `-fexcess-precision=fast`.

### A.2.2.4. Debugging Compatibility

GCC now generates DWARF debugging information that uses more or newer DWARF features than
previously. GDB contained in Red Hat Developer Toolset can handle these features, but versions of
GDB older than 7.0 cannot. GCC can be restricted to only generate debugging information with older
DWARF features by using the `-gdwarf-2` `-gstrict-dwarf` or `-gdwarf-3` `-gstrict-dwarf` options (the latter are handled partially by versions of GDB older than 7.0).

Many tools such as `Valgrind`, `SystemTap`, or third-party debuggers utilize debugging information. It is
suggested to use the `-gdwarf-2` `-gstrict-dwarf` options with those tools.

---

**Note**

Use of Link-time Optimization with debug generation is not yet supported in gcc 4.7 and 4.8 and
so use of the `-flto` and the `-g` options together is unsupported in Red Hat Developer Toolset.

### A.2.2.5. Other Compatibility

GCC is now more strict when parsing command line options, and both `gcc` and `g++` report an error
when invalid command line options are used. In particular, when only linking and not compiling code,
earlier versions of GCC ignored all options starting with `--`. For example, options accepted by the linker
such as `--as-needed` and `--export-dynamic` are not accepted by `gcc` and `g++` anymore, and
should now be directed to the linker using `-Wl,--as-needed` or `-Wl,--export-dynamic` if that is
intended.

Because of the new link-time optimization feature (see Section A.2.2.1.5, “Link-time Optimization”),
support for the older intermodule optimization framework has been removed and the `-combine`
command line option is not accepted anymore.

### A.3. Changes in binutils

Red Hat Developer Toolset 2.0 is distributed with `binutils 2.23.52`, which provides a number of bug
fixes and feature enhancements over the Red Hat Enterprise Linux system version and the version
included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of new features in this release.

The GNU assembler (`as`), GNU linker (`ld`), and other binary tools that are part of binutils are now released under the GNU General Public License, version 3.

A.3.1. GNU Linker

Another ELF linker, `gold`, is now available in addition to `ld`, the existing GNU linker. `gold` is intended to be a drop-in replacement for `ld`, so `ld`'s documentation is intended to be the reference documentation. `gold` supports most of `ld`'s features, except notable ones such as MRI-compatible linker scripts, cross-reference reports (`--cref`), and various other minor options. It also provides significantly improved link time with very large C++ applications.

In Red Hat Developer Toolset 2.0, the `gold` linker is not enabled by default. Users can explicitly switch between `ld` and `gold` by using the `alternatives` mechanism.

A.3.1.1. New Features

Changes Since Red Hat Enterprise Linux 6.4

The following features have been added since the release of binutils included in Red Hat Enterprise Linux 6.4:

- A new `INPUT_SECTION_FLAGS` keyword has been added to the linker script language. This keyword can be used to select input sections by section header flags.
- A new `SORT_BY_INIT_PRIORITY` keyword has been added to the linker script language. This keyword can be used to sort sections by numerical value of the GCC `init_priority` attribute encoded in the section name.
- A new `SORT_NONE` keyword has been added to the linker script language. This keyword can be used to disable section sorting.
- A new linker-provided symbol, `__ehdr_start`, has been added. When producing ELF output, this symbol points to the ELF file header (and nearby program headers) in the program's memory image.

Changes Since Red Hat Enterprise Linux 5.9

The following features have been added since the release of binutils included in Red Hat Enterprise Linux 5.9:

- GNU/Linux targets now support the `STB_GNU_UNIQUE` symbol binding, a GNU extension to the standard set of ELF symbol bindings. The binding is passed on to the dynamic linker, which ensures that in the entire process there is only one symbol with the given name and type in use.

  The implementation of this feature depends on capabilities only found in newer versions of the `glibc` library. Consequently, this feature is currently available in Red Hat Developer Toolset for Red Hat Enterprise Linux 6.

- A new command line option `--no-export-dynamic` has been added. This option can be used to undo the effect of the `-E` and `--export-dynamic` options.
- A new command line option `--warn-alternate-em` has been added. This option can be used to display a warning if an ELF format object file uses an alternate machine code.
- A new linker script function `REGION_ALIAS` has been added. This function can be used to create
alias names of memory regions.

A new command line option `-Ttext-segment address` has been added for ELF-based targets. This option can be used to set the address of the first byte of the text segment.

A new linker script command `INSERT` has been added. This command can be used to augment the default script.

In a linker script input section, it is now possible to specify a file within an archive by using the `archive:file` syntax.

The `--sort-common` command line option now accepts `ascending` and `descending` as optional arguments. This can be used to specify which sorting order to use.

A new command line option `-build-id` has been added for ELF-based targets. This option can be used to generate a unique per-binary identifier embedded in a note section.

A new command line option `--default-script=file_name` (or `-dT file_name`) has been added. This option can be used to specify a replacement for the built-in linker script.

A new command line option `-Bsymbolic-functions` has been added. When creating a shared library, this option will cause references to global function symbols to be bound to the definitions with the shared library, if such exist.

The new command line options `--dynamic-list-cpp-new` and `--dynamic-list-data` have been added, which can be used to modify the dynamic list.

### A.3.1.2. Compatibility Changes

#### Changes Since Red Hat Enterprise Linux 6.4

The following compatibility changes have been made since the release of binutils included in Red Hat Enterprise Linux 6.4:

- The `--copy-dt-needed-entries` command line option is no longer enabled by default. Instead, `-no-copy-dt-needed-entries` is now the default option.
- Evaluation of linker script expressions has been significantly improved. Note that this can negatively affect scripts that rely on undocumented behavior of the old expression evaluation.

#### Changes Since Red Hat Enterprise Linux 5.9

The following compatibility changes have been made since the release of binutils included in Red Hat Enterprise Linux 5.9:

- The `--add-needed` command line option has been renamed to `--copy-dt-needed-entries` in order to avoid confusion with the `--as-needed` option.
- For GNU/Linux systems, the linker no longer processes any relocations made against symbols of the `STT_GNU_IFUNC` type. Instead, it emits them into the resulting binary for processing by the loader.

#### Note

The implementation of this feature depends on capabilities only found in newer versions of the `glibc` library. Consequently, this feature is currently available in Red Hat Developer Toolset for Red Hat Enterprise Linux 6.

- The `--as-needed` command line option has been adapted to link in a dynamic library in the following two cases:
  1. if the dynamic library satisfies undefined symbols in regular objects, and
  2. if the dynamic library satisfies undefined symbols in other dynamic libraries unless the library
is already found in a **DT_NEEDED** entry of one of the libraries that are already linked.

- The **-l:** *file_name* command line option now searches the library path for a file name called *file_name* without adding the .a or .so file extension.

### A.3.2. GNU Assembler

#### A.3.2.1. New Features

**Changes Since Red Hat Enterprise Linux 6.4**
The following features have been added since the release of binutils included in Red Hat Enterprise Linux 6.4:

- The GNU Assembler no longer requires double ampersands in macros.
- A new **--compress-debug-sections** command line option has been added to enable compression of DWARF debug information sections in the relocatable output file. Compressed debug sections are currently supported by the **readelf**, **objdump**, and **gold** tools, but not by **ld**.
- Support for **.bundle_align_mode**, **.bundle_lock**, and **.bundle_unlock** directives for x86 targets has been added.
- On x86 architectures, the GNU Assembler now allows **rep bsf**, **rep bsr**, and **rep ret** syntax.

**Changes Since Red Hat Enterprise Linux 5.9**
The following features have been added since the release of binutils included in Red Hat Enterprise Linux 5.9:

- GNU/Linux targets now support **gnu_unique_object** as a value of the .type pseudo operation. This value can be used to mark a symbol as globally unique in the entire process.
- Support for the new discriminator column in the DWARF line table with a discriminator operand for the .loc directive has been added.
- The .type pseudo operation now accepts a type of **STT_GNU_IFUNC**. This can be used to indicate that if the symbol is the target of a relocation, its value should not be used. Instead, the function should be invoked and its result used as the value.
- A new pseudo operation **.cfi_val_encoded_addr** has been added. This pseudo operation can be used to record constant addresses in unwind tables without runtime relocation.
- A new command line option **-msse-check=[none|error|warning]** has been added for x86 targets.
- The -a command line option now accepts **g** as a valid sub-option. This combination can be used to enable assembly listings with additional information about the assembly, including the list of supplied command line options or the assembler version.
- A new command line option **-msse2avx** has been added for x86 targets. This option can be used to encode SSE instructions with VEX prefix.
- x86 targets now support the Intel XSAVE, EPT, MOVBE, AES, PCLMUL, and AVX/FMA instructions.
- New command line options **-march=cpu[+extension...]**, **-mtune=cpu**, **-mmnemonic=[att|intel]**, **-msyntax=[att|intel]**, **-mindex-reg**, **-mnaked-reg**, and **-mold-gcc** have been added for x86 targets.
- New pseudo operations **.string16**, **.string32**, and **.string64** have been added. These pseudo operations be used to generate wide character strings.
- The i386 port now supports the SSE5 instruction set.
- A new pseudo operation **.reloc** has been added. This pseudo operation serves as a low-level
interface for creating relocations.

A.3.3. Other Binary Tools

A.3.3.1. New Features

Changes Since Red Hat Developer Toolset 1.1
The following features have been added since the release of binutils included in Red Hat Developer Toolset 1.1:

- A manual page for the dwp utility has been added.
- The binary tools now provide support for the AMD Family 15h processors, models 02h and 10-1fh.

Changes Since Red Hat Enterprise Linux 6.4
The following features have been added since the release of binutils included in Red Hat Enterprise Linux 6.4:

- The readelf and objdump tools can now display the contents of the .debug.macro sections.
- New --dwarf-start and --dwarf-end command line options have been added to the readelf and objdump tools. These options are used by the new Emacs mode (see the dwarf-mode.el file).
- A new --interleave-width command line option has been added to the objcopy tool to allow the use of the --interleave to copy a range of bytes from the input to the output.
- A new --dyn-syms command line option has been added to the readelf tool. This option can be used to dump dynamic symbol table.
- A new tool, elfedit, has been added to binutils. This tool can be used to directly manipulate ELF format binaries.
- A new command line option --addresses (or -a for short) has been added to the addr2line tool. This option can be used to display addresses before function and source file names.
- A new command line option --pretty-print (or -p for short) has been added to the addr2line tool. This option can be used to produce human-readable output.
- Support for dwz -m optimized debug information has been added.
- The devtoolset-2-binutils-devel package now provides the demangle.h header file.

Changes Since Red Hat Enterprise Linux 5.9
The following features have been added since the release of binutils included in Red Hat Enterprise Linux 5.9:

- A new command line option --insn-width=width has been added to the objdump tool. This option can be used to specify the number of bytes to be displayed on a single line when disassembling instructions.
- A new command line option --relocated-dump=name|number has been added to the readelf tool. This option can be used to display the relocated contents of a section as a sequence of bytes.
- A new command line option --external-symbols-table=filename has been added to the gprof tool. This option can be used to read a symbol table from a certain file.
- bfd now supports a plugin target, which can be used to get basic support for new file formats by having the plugin target load the same shared objects used by gold.
- The --dwarf (or -W for short) command line option of the objdump tool has been adapted to be as flexible as the --debug-dump (or -w) option of readelf.
New command line options `--prefix=prefix` and `--prefix-strip=level` have been added to the `objdump` tool. These options can be used to add absolute paths for the `--source` (or `-S` for short) option.

A new command line option `-wL` has been added to the `readelf` tool. This option can be used to dump decoded contents of the `.debug_line` section.

“Thin” archives are now supported. Instead of containing object files, such archives contain just pathnames pointing to those files.

A new command line option `-F` has been added to the `objdump` tool. This option can be used to include file offsets in the disassembly.

A new command line option `-c` has been added to the `readelf` tool. This option can be used to allow string dumps of archive symbol index.

The i386 port now supports the SSE5 instruction set.

A new command line option `-p` has been added to the `readelf` tool. This option can be used to allow string dumps of sections.

### A.3.3.2. Compatibility Changes

#### Changes Since Red Hat Enterprise Linux 5.9

The following compatibility changes have been made since the release of binutils included in Red Hat Enterprise Linux 5.9:

- The `--as-needed` command line option has been adapted to link in a dynamic library in the following two cases:
  1. if the dynamic library satisfies undefined symbols in regular objects, and
  2. if the dynamic library satisfies undefined symbols in other dynamic libraries unless the library is already found in a `DT_NEEDED` entry of one of the libraries that are already linked.

### A.4. Changes in elfutils

Red Hat Developer Toolset 2.0 is distributed with `elfutils 0.155`, which provides a number of bug fixes and feature enhancements over the Red Hat Enterprise Linux system version and the version included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of new features in this release.

#### A.4.1. Changes Since Red Hat Developer Toolset 1.1

The following features have been added since the release of elfutils included in Red Hat Developer Toolset 1.1:

- In the `libdw` library, the `DW_LANG_Objc` constant has been correctly renamed to `DW_LANG_ObjC`. Note that any existing source code that uses the old name needs to be updated accordingly.
- The `libdw` library now supports new constants `DW_ATE_UTF` and `DW_OP_GNU_parameter_ref`. In addition, it also defines a family of constants to support the `.debug_macro` section, namely `DW_MACRO_GNU_define`, `DW_MACRO_GNU_undef`, `DW_MACRO_GNU_start_file`, `DW_MACRO_GNU_end_file`, `DW_MACRO_GNU_define_indirect`, `DW_MACRO_GNU_undef_indirect`, and `DW_MACRO_GNU_transparent_include`.
- When working with the `libelf` library, both `elf32_xlatetomd` and `elf64_xlatetomd` now work for cross-endian ELF note data.
- The `elf_getshdr()` function provided by the `libelf` library has been corrected to work consistently on non-mmapped ELF files after making the `elf_cntl(ELF_C_FDREAD)` function call.
- The `libelf` library now supports `ar` archives with a 64-bit symbol table.
The `eu-readelf` command is now able to display the contents of the `.debug_macro` section.

The `eu-readelf` command now correctly recognizes the `DW_OP_GNU_parameter_ref` DWARF GNU extension opcode in location expressions.

A.4.2. Changes Since Red Hat Enterprise Linux 6.4
The following features have been added since the release of elfutils included in Red Hat Enterprise Linux 6.4:

- The `libdw` library now handles compressed debuginfo sections. The `dwarf_highpc()` function now handles the DWARF 4 `DW_AT_high_pc` constant form.
- The `eu-elflint` utility now accepts executables produced by the `gold` linker.
- The `eu-nm` utility now supports C++ demangling.
- The `eu-ar` utility now supports a new modifier `D` for deterministic output with no UID, GID, ormtime info. The `U` modifier is the inverse.
- The `eu-readelf` utility can now print SDT ELF notes (SystemTap probes) and the `.gdb_index` GDB section. It can now also print `DW_OP_GNU_entry_value` and `DW_AT_GNU_call_site` families of DIE attributes.
- The `eu-strip` utility now recognizes a new command line option, `--reloc-debug-sections`.

A.4.3. Changes Since Red Hat Enterprise Linux 5.9
In addition to the above changes, the following features have been added since the release of elfutils included in Red Hat Enterprise Linux 5.9:

- DWARF 4 is now supported. As well, support for `DW_OP_GNU_implicit_pointer` and `STB_GNU_UNIQUE` has been added.
- The `libdwfl` library now supports automatic decompression of files compressed with `gzip`, `bzip2` and `lzma`, and of Linux kernel images made with `gzip`, `bzip2` or `lzma`. Files named with compression suffixes are searched for Linux kernel images. Core file support was improved. Support has been added for decoding DWARF CFI into location description form. Support has been added for some new DWARF 3 expression operations, which were previously omitted. A new function, `dwfl_dwarf_line()`, has been added.
- The `eu-elfcmp` utility now supports a new command line option `--ignore-build-id` to ignore differing build ID bits. The new option `--verbose` (or `-l` for short) prints all differences.
- The `eu-strip` utility now recognizes a new command line option `--strip-sections` to remove section headers entirely.
- The `libdw` library now has new functions `dwarf_next_unit()`, `dwarf_offdie_types()`, `dwarf_lineisa()`, `dwarf_linediscriminator()`, `dwarf_lineop_index()`, `dwarf_getlocation_implicit_pointer()`, and `dwarf_aggregate_size()`.
- The `eu-addr2line` utility now recognizes a new command line option `--flags` (or `-F` for short) to print more DWARF line information details.
- The `libelf` library now supports using more than 65536 program headers in a file. In addition, a new function `elf_getphdrnum()` has been added.
- The `eu-addr2line` utility now accepts the `--section=` option (or `-j name` for short) in the interests of binutils compatibility.
- `libcpu` Intel SSE4 disassembler support has been added.
- The `eu-readelf` utility now implements call frame information and exception handling dumping. The `-e` command line option has been added; this is enabled implicitly by `-a`.  

121
A.5. Changes in dwz

Red Hat Developer Toolset 2.0 is distributed with dwz 0.11, which provides a number of bug fixes and enhancements over the version included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of changes in this release.

A.5.1. Changes Since Red Hat Developer Toolset 1.1

The following features have been added since the release of dwz included in Red Hat Developer Toolset 1.1:

- The DW_FORM_data4, DW_FORM_data8, and DW_AT_high_pc attributes have been optimized.
- The dwz utility now allocates more memory when recomputing abbreviations and no longer terminates unexpectedly.
- The dwz utility no longer crashes when processing debugging information that contains several copies of the same Debugging Information Entry (DIE) within the same compilation unit.
- The dwz utility no longer writes an incorrect DW_FORM code for a compilation unit version.
- The dwz utility now supports version 8 of the .gdb_index section.

A.6. Changes in GDB

Red Hat Developer Toolset 2.0 is distributed with GDB 7.6, which provides a number of bug fixes and feature enhancements over the Red Hat Enterprise Linux system version and the version included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of new features in this release.

A.6.1. Changes Since Red Hat Developer Toolset 1.1

The following features have been added since the release of GDB included in Red Hat Developer Toolset 1.1:

- Target record has been renamed to record-full. Consequently, you can now use the record full command to record or replay an execution log. In addition, the following commands have been renamed:
  - The set record insn-number-max and show record insn-number-max commands have been renamed to set record full insn-number-max and show record full insn-number-max.
  - The set record memory-query and show record memory-query commands have been renamed to set record full memory-query and show record full memory-query.
  - The set record stop-at-limit and show record stop-at-limit commands have been renamed to set record full stop-at-limit and show record full stop-at-limit.
- A new record target, record-btrace, has been added. This target uses hardware support to record the control flow of a process and can be enabled by using the record btrace command. This record target does not support replaying the execution.

Important

The record-btrace target is only available on Intel Atom processors and requires the Linux kernel in version 2.6.32 or later.
- New `record instruction-history` and `record function-call-history` commands have been added. These commands allow you to view information about an execution log without having to replay it. The `record instruction-history` command displays the execution history at instruction granularity and the `record function-call-history` displays the execution history at function granularity. The commands are only supported by the `record btrace` command.
- A new command line option, `-nh`, has been added. This option allows you to disable automatic loading of the `~/.gdbinit` file without disabling other initialization files.
- The `-epoch` command line option has been removed. This option was used by GDB mode in Epoch, a deprecated clone of the Emacs text editor.
- The `ptype` and `whatis` commands have been updated to accept an argument to control the type formatting.
- The `info proc` command has been updated to work on some core files.
- The `cd` command has been enhanced and no longer requires a directory path as its first argument. When executed with no arguments, the command now changes to the home directory.
- GDB now uses GNU v3 ABI as the default C++ ABI. This has been the default option for GCC since November 2000.
- The `info tracepoints` command has been enhanced to display `installed on target` or `not installed on target` for each non-pending location of a tracepoint.
- A new command, `fo`, has been added. This command serves as a shorter variant of the `forward-search` command.
- A new command, `catch signal`, has been added. This command can be used to catch signals by their names and is similar to the `handle` command, but also allows you to attach additional conditions or commands.
- A new command, `maint info bfd`, has been added. This command can be used to list all binary files (BFDs) opened by GDB.
- Two new commands, `python-interactive [command]` and its shorter variant `pi [command]`, have been added. These commands allow you to start an interactive Python prompt or evaluate a Python command and print the results to standard output.
- A new command, `py [command]`, has been added. This command serves as a shorter variant of the `python [command]` command.
- New `enable type-printer [name...]` and `disable type-printer [name...]` commands have been added. These commands allow you to enable or disable type printers.
- New `set print type methods on|off` and `show print type methods` commands have been added. These commands allow you to control whether method declarations are displayed by the `ptype` command. This functionality is enabled by default.
- New `set print type typedefs on|off` and `show print type typedefs` commands have been added. These commands allow you to control whether `typedef` definitions are displayed by the `ptype` command. This functionality is enabled by default.
- New `set filename-display basename|relative|absolute` and `show filename-display` commands have been added. These commands allow you to control the way in which file names are displayed: the `basename` option displays only the base name of a file name, `relative` displays a path relative to the compilation directory, and `absolute` displays an absolute path to the file. The default option is `relative` to preserve the previous behavior.
- New `set trace-buffer-size` and `show trace-buffer-size` commands have been added. These commands allow you to control the size of the trace buffer for a target.
- New `set remote trace-buffer-size-packet auto|on|off` and `show remote trace-buffer-size-packet` commands have been added. These commands allow you to control the
use of the remote protocol `QTBuffer::size` packet.

- New set debug notification and show debug notification commands have been added. These commands allow you to control whether to display debugging information for asynchronous remote notification. This functionality is disabled by default.
- New convenience functions `$memeq(buf1, buf2, length)`, `$streq(str1, str2)`, `$strlen(str)`, and `$regex(str, regex)` have been added.

The following changes have been made to the Python scripting support since the release of GDB included in Red Hat Developer Toolset 1.1:

- Users can now create vectors by using the `gdb.Type.vector()` method.
- The `atexit.register()` method is now supported.
- Users can now pretty-print types by using the Python API.
- In addition to Python 2.4 and later, GDB now also supports Python 3.
- A new class, `gdb.Architecture`, has been added. This class exposes the internal representation of the architecture in the Python API.
- A new method, `Frame.architecture`, has been added. This method can be used to return the `gdb.Architecture` object corresponding to the frame's architecture.
- Frame filters and frame decorators have been added.

The following MI changes have been made since the release of GDB included in Red Hat Developer Toolset 1.1:

- A new async record, `=cmd-param-changed`, has been added. This async record reports that a command parameter has changed.
- A new async record, `=traceframe-changed`, has been added. This async record reports that a trace frame has been changed by using the `tfind` command.
- New async records `=tsv-created`, `=tsv-deleted`, and `=tsv-modified` have been added. These async records report that a trace state variable has been created, deleted, or modified.
- New async records `=record-started` and `=record-stopped` have been added. These async records report that a process record has been started or stopped.
- A new async record, `=memory-changed`, has been added. This async record reports that the memory has changed.
- When the source is requested, the `-data-disassemble` command now includes a new `fullname` field containing an absolute path to the source file name.
- A new optional parameter, `COUNT`, has been added to the `-data-write-memory-bytes` command. This parameter can be used to allow pattern filling of memory areas.
- New commands `-catch-load` and `-catch-unload` have been added. These commands can be used to intercept shared library load/unload events.
- The response to breakpoint commands and breakpoint async records now includes a new `installed` field. This field reports the current state of each non-pending tracepoint location: when the tracepoint is installed, the value of this field is `y`, otherwise the value is `n`.
- The output of the `-trace-status` command now includes a new `trace-file` field. This field is only present when examining a trace file and contains the name of this file.
- The `fullname` field is now always present along with the `file` field. This field is included even if GDB cannot find the file.

A number of new remote packets have been added since the release of GDB included in Red Hat Developer Toolset 1.1. See Table A.3, “New Remote Packets” for a complete list.
Table A.3. New Remote Packets

<table>
<thead>
<tr>
<th>Remote Packet</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QTBuffer:size</td>
<td>Sets the size of the trace buffer. The remote stub reports support for this packet to the qSupported query.</td>
</tr>
<tr>
<td>Qbtrace:bts</td>
<td>Enables branch tracing based on Branch Trace Store (BTS) for the current thread. The remote stub reports support for this packet to the qSupported query.</td>
</tr>
<tr>
<td>Qbtrace:off</td>
<td>Disables branch tracing for the current thread. The remote stub reports support for this packet to the qSupported query.</td>
</tr>
<tr>
<td>qXfer:btrace:read</td>
<td>Reads the traced branches for the current thread. The remote stub reports support for this packet to the qSupported query.</td>
</tr>
<tr>
<td>qXfer:libraries-svr4:read</td>
<td>The previously unused annex of the qXfer:libraries-svr4:read packet is now used to support passing of an argument list. The remote stub reports support for this argument list to the qSupported query.</td>
</tr>
<tr>
<td></td>
<td>The defined arguments are start and prev. These arguments are used to reduce work necessary for updating the library list and significantly speed up the process.</td>
</tr>
</tbody>
</table>

A.6.2. Changes Since Red Hat Enterprise Linux 6.4

The features below have been added since the release of GDB included in Red Hat Enterprise Linux 6.4.

New Features

- Support for linespecs has been improved (in particular, a more consistent handling of ambiguous linespecs, some support for labels in the program's source, and FILE:LINE support now extends to further linespecs types). Breakpoints are now set on all matching locations in all inferiors and will be updated according to changes in the inferior.
- New inferior control commands `skip function` and `skip file` have been added. These commands can be used to skip certain functions and files when stepping.
- The `info threads` command now displays the thread name as set by `prctl` or `pthread_setname_np`. In addition, new commands `thread name` and `thread find` have been added. The `thread name` command accepts a name as an argument and can be used to set the name of the current thread. The `thread find` command accepts a regular expression and allows the user to find threads that match it.
- GDB now provides support for reading and writing a new `.gdb_index` section. The command `gdb-add-index` can be used to add `.gdb_index` to a file, which allows GDB to load symbols from that file faster. Note that this feature is already present in Red Hat Enterprise Linux 6.1 and later.
- The `watch` command has been adapted to accept `-location` as an optional argument.
- Two new special values can now be used when specifying the current search path for `libthread_db: $sdir` represents the default system locations of shared libraries, and `$pdir` stands for the directory with the `libthread` that is used by the application.
- A new command `info macros` has been added. This command accepts linespec as an optional argument and can be used to display the definitions of macros at that linespec location. Note that in order to do this, the debugged program must be compiled with the `-g3` command line option to have
A new command alias has been added. This command can be used to create an alias of an existing command.

The info macro command now accepts -all and -- as valid options.

To display a function parameter’s entry value (that is, the value at the time of function entry), the suffix @entry can be added to the parameter. GDB now displays @entry values in backtraces, if available.

New set print entry-values and show print entry-values commands have been added. The set print entry-values command accepts both, compact, default, if-needed, no, only, and preferred as valid arguments and can be used to enable printing of function arguments at function entry. The show print entry-values command can be used to determine whether this feature is enabled.

New set debug entry-values and show debug entry-values commands have been added. The set debug entry-values command can be used to enable printing of debugging information for determining frame argument values at function entry and virtual tail call frames.

!command has been added as an alias of shell command.

The watch command now accepts mask mask_value as an argument. This can be used to create masked watchpoints.

New set extended-prompt and show extended-prompt commands have been added. The set extended-prompt command enables support for a defined set of escape sequences that can be used to display various information. The show extended-prompt command can be used to determine whether the extended prompt is enabled.

New set basenames-may-differ and show basenames-may-differ commands have been added. The set basenames-may-differ command enables support for source files with multiple base names. The show basenames-may-differ command can be used to determine whether this support is enabled. The default option is off to allow faster GDB operations.

A new command line option -ix (or --init-command) has been added. This option acts like -x (or --command), but is executed before loading the debugged program.

A new command line option -iex (or --init-eval-command) has been added. This option acts like -ex (or --eval-command), but is executed before loading the debugged program.

The info os command has been changed and can now display information on several objects managed by the operating system, in particular:

- The info os procgroups command lists process groups.
- The info os files command lists file descriptors.
- The info os sockets command lists internet-domain sockets.
- The info os shm command lists shared-memory regions.
- The info os semaphores command lists semaphores.
- The info os msg command lists message queues.
- The info os modules command lists loaded kernel modules.

GDB now has support for Static Defined Tracing (SDT) probes. Currently, the only implemented backend is for SystemTap probes (the sys/sdt.h header file). You can set a breakpoint by using the new -probe, -pstat, or -probe-stap options, and inspect the probe arguments by using the new $_probe_arg family of convenience variables.

The symbol-reloading option has been deleted.

gdbserver now supports STDIO connections, for example:
GDB is now able to print flag enums. In a flag enum, all enumerator values have no bits in common when pairwise AND-ed. When GDB prints a value whose type is a flag enum, GDB shows all the constants; for example, for enum E { ONE = 1, TWO = 2}:

```
(gdb) print (enum E) 3
$1 = (ONE | TWO)
```

The file name part of a linespec now matches trailing components of a source file name. For example, `break gcc/expr.c:1000` now sets a breakpoint in the `build/gcc/expr.c` file, but not in `build/libcpp/expr.c`.

The `info proc` and `generate-core-file` commands now work on remote targets connected to `gdbserver`.

The command `info catch` has been removed.

The Ada-specific `catch exception` and `catch assert` commands now accept conditions at the end of the command.

The `info static-tracepoint-marker` command now works on native targets with an in-process agent.

GDB can now set breakpoints on inline functions.

The `.gdb_index` section has been updated to include symbols for inline functions. By default, GDB now ignores older `.gdb_index` sections until their `.gdb_index` sections can be recreated. The new command `set use-deprecated-index-sections on` causes GDB to use any older `.gdb_index` sections it finds. If this option is set, the ability to set breakpoints on inline functions is lost in symbol files with older `.gdb_index` sections.

The `.gdb_index` section has also been updated to record more information about each symbol.

GDB now provides Ada support for GDB/MI Variable Objects.

GDB now supports breakpoint always-inserted mode in the `record` target.

`gdbserver` now supports evaluation of breakpoint conditions. Note that you can instruct GDB to send the breakpoint conditions in bytecode form, but `gdbserver` only reports the breakpoint trigger to GDB when its condition evaluates to true.

The `z0/z1` breakpoint insertion packets have been extended to carry a list of conditional expressions over to the remote stub depending on the condition evaluation mode. You can use the `set remote conditional-breakpoints-packet` command to control the use of this extension.

A new RSP packet `QProgramSignals` can be used to specify the signals the remote stub can pass to the debugged program without GDB involvement.

A new command `-info-os` has been added as the MI equivalent of `info os`.

Output logs, such as `set logging` and related, now include MI output.

New `set use-deprecated-index-sections on|off` and `show use-deprecated-index-sections on|off` commands have been added. These commands allow you to control the use of deprecated `.gdb_index` sections.

New `catch load` and `catch unload` commands have been added. These commands allow you to stop execution of a debugged program when a shared library is loaded or unloaded.

A new command `enable count` has been added. This command allows you to auto-disable a breakpoint after several hits.

A new command `info vtbl` has been added. This command allows you to show the virtual method tables for C++ and Java objects.
A new command `explore` has been added. It supports two subcommands `explore value` and `explore type`, and allows you to recursively explore values and types of expressions. Note that this command is only available with Python-enabled GDB.

A new command `dprintf location, format, args...` has been added. This command allows you to create a dynamic `printf`-type breakpoint, which performs a `printf`-like operation and then resumes program execution.

New `set print symbol` and `show print symbol` commands have been added. These commands allow you to control whether GDB attempts to display the symbol, if any, that corresponds to addresses it prints. This functionality is enabled by default, but you can restore the previous behavior by running the `set print symbol off` command.

New `set breakpoint condition-evaluation` and `show breakpoint condition-evaluation` commands have been added. These commands allow you to control whether breakpoint conditions are evaluated by GDB (the `host` option), or by `gdbserver` (the `target` option). The default option, `auto`, chooses the most efficient available mode.

New `set dprintf-style gdb|call|agent` and `show dprintf-style` commands have been added. These commands allow you to control the way in which a dynamic `printf` is performed: the `gdb` option requests a GDB `printf` command, `call` causes `dprintf` to call a function in the inferior, and `agent` requests that the target agent such as `gdbserver` does the printing.

New `set dprintf-function expression`, `show dprintf-function`, `set dprintf-channel expression`, and `show dprintf-channel` commands have been added. These commands allow you to set the function and optional first argument to the call when using the `call` style of dynamic `printf`.

New `set disconnected-dprintf on|off` and `show disconnected-dprintf` commands have been added. These commands allow you to control whether agent-style dynamic `printfs` continue to be in effect after GDB disconnects.

The following changes have been made to the C++ language support since the release of the GNU Debugger included in Red Hat Enterprise Linux 6.2:

- When debugging a template instantiation, parameters of the template are now put in scope.

The following changes have been made to the Python scripting support since the release of the GNU Debugger included in Red Hat Enterprise Linux 6.2:

- The `register_pretty_printer` function in module `gdb.printing` now takes an optional `replace` argument.
- The `maint set python print-stack on|off` command has been deprecated and will be deleted in GDB 7.5. The new command `set python print-stack none|full|message` has replaced it.
- A prompt substitution hook (`prompt_hook`) is now available to the Python API.
- A new Python module `gdb.prompt` has been added to the GDB Python modules library.
- Python commands and convenience-functions located in `data_directory/python/gdb/command/` and `data_directory/python/gdb/function/` are now automatically loaded on GDB start-up.
- Blocks now provide four new attributes: `global_block`, `static_block`, `is_static`, and `is_global`.
- The `gdb.breakpoint` function has been deprecated in favor of `gdb.breakpoints`.
- A new class `gdb.FinishBreakpoint` is provided.
- Type objects for `struct` and `union` types now allow access to the fields using standard Python
dictionary (mapping) methods.

- A new event `gdb.new_objfile` has been added.
- A new function `deep_items` has been added to the `gdb.types` module.
- The function `gdb.Write` now accepts an optional keyword `stream`.
- Parameters can now be sub-classed in Python, which allows for implementation of the `get_set_doc` and `get_show_doc` functions.
- Symbols, Symbol Table, Symbol Table and Line, Object Files, Inferior, Inferior Thread, Blocks, and Block Iterator APIs now have an `is_valid` method.
- Breakpoints can now be sub-classed in Python, which allows for implementation of the `stop` function that is executed each time the inferior reaches that breakpoint.
- A new function `gdb.lookup_global_symbol` has been added. This function can be used to look up a global symbol.
- GDB values in Python are now callable if the value represents a function.
- A new module `gdb.types` has been added.
- A new module `gdb.printing` has been added.
- New commands `info pretty-printers`, `enable pretty-printer`, and `disable pretty-printer` have been added.
- A new `gdb.parameter("directories")` function call is now available.
- A new function `gdb.newest_frame` has been added. This function can be used to return the newest frame in the selected thread.
- The `gdb.InferiorThread` class now supports a new `name` attribute.
- Support for inferior events has been added. Python scripts can now add observers in order to be notified of events occurring in the process being debugged.
- GDB commands implemented in Python can now be put in the `gdb.COMMAND_USER` command class.
- The `maint set python print-stack on|off` command has been removed and replaced by `set python print-stack`.
- A new class `gdb.printing.FlagEnumerationPrinter` has been added. This class can be used to apply flag enum-style pretty-printing to enums.
- The `gdb.lookup_symbol` function now works correctly when there is no current frame.
- The `gdb.Symbol` object now has an additional attribute `line`. This attribute holds the line number in the source at which the symbol was defined.
- The `gdb.Symbol` object now has an additional attribute `needs_frame`, and a new method `value`. The `needs_frame` attribute indicates whether the symbol requires a frame to compute its value, and the `value` method computes the symbol's value.
- The `gdb.Value` object now has a new method `referenced_value`. This method can be used to dereference a pointer as well as C++ reference values.
- The `gdb.Symtab` object now has two new methods, `global_block` and `static_block`. These methods return the global and static blocks (as `gdb.Block` objects) of the underlying symbol table respectively.
- A new method `gdb.find_pc_line` returns the `gdb.Symtab_and_line` object associated with a PC value.
- The `gdb.Symtab_and_line` object now has an additional attribute `last`. This attribute holds the end of the address range occupied by the code for the current source line.

Compatibility Changes
A new command `info auto-load` has been added and can be used to display the status of various automatically loaded files. The `info auto-load gdb-scripts` command lists automatically loaded canned sequences of commands, `info auto-load python-scripts` displays the status of automatically loaded Python scripts, `info auto-load local-gdbinit` displays whether a local `.gdbinit` file in the current working directory is loaded, and `info auto-load libthread-db` displays whether the inferior-specific thread debugging shared library is loaded.

New commands `set auto-load` and `show auto-load` have been added and can be used to control automatic loading of files:

- The `set auto-load gdb-scripts` and `show auto-load gdb-scripts` commands control automatic loading of GDB scripts.
- The `set auto-load python-scripts` and `show auto-load python-scripts` commands control automatic loading of Python scripts.
- The `set auto-load local-gdbinit` and `show auto-load local-gdbinit` commands control automatic loading of `.gdbinit` from the current working directory.
- The `set auto-load libthread-db` and `show auto-load libthread-db` commands control automatic loading of inferior-specific `libthread_db`.
- The `set auto-load scripts-directory` and `show auto-load scripts-directory` commands control the list of directories from which to automatically load GDB and Python scripts.
- The `set auto-load safe-path` and `show auto-load safe-path` commands control the list of directories from which it is safe to automatically load all previously mentioned items.
- The `set debug auto-load` and `show debug auto-load` commands control displaying of debugging information for all previously mentioned items.

The `set auto-load off` command can be used to disable automatic loading globally. You can also use `show auto-load` with no subcommand to display current settings of all previously mentioned items.

The `maint set python auto-load on|off` command has been replaced with `set auto-load python-scripts on|off`.

The `maintenance print section-scripts` command has been renamed to `info auto-load python-scripts [pattern]` and is no longer classified as a maintenance-only command.

Support for the Guile extension language has been removed.

The GNU Debugger has been adapted to follow GCC's rules on accessing volatile objects when reading or writing target state during expression evaluation.

### A.6.3. Changes Since Red Hat Enterprise Linux 5.9

In addition to the above changes, the features below have been added since the release of GDB included in Red Hat Enterprise Linux 5.9.

#### New Features

- For remote targets, debugging of shared libraries is now supported by default.
- New commands `set observer` and `show observer` have been added. The `set observer` command accepts `on` or `off` as an argument and can be used to allow or disallow the GNU Debugger to affect the execution of the debugged program. Use the `show observer` command to determine whether observer mode is enabled.
- A new convenience variable `$_thread` has been added. This variable stores the number of the current thread.
- The `source` command now accepts `-s` as a valid option. This option can be used to search for the
script in the source search path regardless of the path in the file name.

- Support for tracepoints, including fast and static tracepoints, has been added to `gdbserver`.
- The `--batch` command line option has been adapted to disable pagination and queries.
- Direct support for the reading and writing byte, word, and double-word x86 general purpose registers such as `$al` has been added.
- The `commands` command now accepts a range of breakpoints as an argument.
- The `rbreak` command now accepts a file name as part of its argument. This can be used to limit the functions selected by the supplied regular expression to those that are defined in the specified file.
- Support for multi-program (sometimes referred to as multi-executable or multi-exec) debugging has been added. In particular, the GNU Debugger now supports the following commands:
  - The `add-inferior` command can be used to add a new inferior.
  - The `clone-inferior` command can be used to create a copy of an inferior with the same executable loaded.
  - The `remove-inferior` command accepts an inferior ID as an argument and can be used to remove an inferior.
- Support for trace state variables has been added. In particular, the GNU Debugger now supports the following commands:
  - The `tvariable $variable_name [ = expression]` command can be used to define or modify a trace state variable.
  - The `info tvariables` command can be used to display a list of currently defined trace state variables and their values.
  - The `delete tvariable $variable_name...` command can be used to delete one or more trace state variables.
- A new `ftrace` has been added. This command accepts a function name, a line number, or an address as an argument, and can be used to define a fast tracepoint at that location.
- Support for disconnected tracing, trace files, and circular trace buffer has been added.
- A new `teval` command has been added. This command accepts one or more expressions to evaluate at a tracepoint.
- The GNU Debugger has been adapted to parse the `0b` prefix of binary numbers exactly the same way as the GNU Compiler Collection.
- The GNU Debugger now supports the following commands for process record and replay:
  - New commands `set record memory` and `show record memory` have been added. The `set record memory` command accepts `on` or `off` as an argument and can be used to enable or disable stopping the inferior when a memory change of the next instruction cannot be recorded. Use the `show record memory-query` command to determine whether this feature is enabled.
  - A new command `record save` has been added. This command accepts a file name as an argument and can be used to save the execution log to a file.
  - A new command `record restore` has been added. This command accepts a file name as an argument and can be used to restore the execution log from a file.
  - A new command `eval` has been added. This command accepts a format string followed by one or more arguments, transforms it to a command, and then executes it.
  - A new command `save breakpoints` has been added. This command accepts a file name as an argument and can be used to store all currently defined breakpoints to a file. To restore the saved breakpoints from this file, use the `source` command.
- New commands `set may-write-registers`, `set may-write-memory`, `set may-insert-breakpoints`, `set may-insert-tracepoints`, `set may-insert-fast-tracepoints`, and
set may-interrupt have been added. All of these commands accept either on or off as an argument, and can be used to set individual permissions for the target.

A new command main info program-spaces has been added. This command can be used to display information about currently loaded program spaces.

New commands set remote interrupt-sequence and show remote interrupt-sequence have been added. The set remote interrupt-sequence command accepts Ctrl-C, BREAK, and BREAK-g as valid arguments, and can be used to specify which interrupt sequence to send to the remote target in order to interrupt its execution. Use the show remote interrupt-sequence to determine the current setting.

New commands set remote interrupt-on-connect and show remote interrupt-on-connect have been added. The set remote interrupt-on-connect accepts either on or off as an argument, and can be used to enable sending an interrupt sequence to the remote target when the GNU Debugger connects to it. Use the show remote interrupt-on-connect command to determine whether this feature is enabled.

The set remotedbreak and show remotedbreak commands have been deprecated and users are advised to use set remote interrupt-sequence and show remote interrupt-sequence instead.

The disassemble command has been adapted to accept two arguments in the form of start,+length.

The source command can now be used to read commands from Python scripts.

The following changes have been made to the C++ language support since the release of the GNU Debugger included in Red Hat Enterprise Linux 5.8:

- Argument-dependent lookup (ADL) now directs function search to the namespaces of its arguments regardless of whether the namespace has been imported.
- In addition to member operators, the GNU Debugger can now look up operators that are:
  - defined in the global scope,
  - defined in a namespace and imported via the using directive,
  - implicitly imported from an anonymous namespace, or
  - the argument-dependent lookup (ADL operators).
- Support for printing of static const class members that are initialized in the class definition has been enhanced.
- Support for importing of namespaces has been added.
- The C++ expression parser has been adapted to handle the cast operators static_cast<>,
dynamic_cast<>., const_cast<>., and reinterpret_cast<>.

The following changes have been made to the Python scripting support since the release of the GNU Debugger in Red Hat Enterprise Linux 5.8:

- The GNU Debugger is now installed with a new directory located at /opt/rh/devtoolset-2/root/usr/share/gdb/python/. This directory serves as a standard location for Python scripts written for GDB.
- The Python API has been adapted to provide access to symbols, symbol tables, program spaces, breakpoints, inferiors, threads, and frame’s code blocks. Users are now also allowed to create custom GDB parameters from the API and manipulate them by using the set and show commands.
- New functions gdb.target_charset, gdb.target_wide_charset, gdb.progspace,
gdb.current_progspace, and gdb.string_to_argv have been added.
- A new exception gdb.GdbError has been added.
The GNU Debugger now searches pretty-printers in the current program space.
The GNU Debugger can now enable or disable pretty-printers individually.
The GNU Debugger has been adapted to look for names of Python scripts to automatically load in a special section named `.debug_gdb_scripts`.

### A.7. Changes in strace

Red Hat Developer Toolset 2.0 is distributed with strace 4.7, which provides a number of bug fixes and feature enhancements over the Red Hat Enterprise Linux system version. Below is a comprehensive list of new features in this release.

#### A.7.1. Changes Since Red Hat Enterprise Linux 6.4 and 5.9

The following features have been added since the release of strace in Red Hat Enterprise Linux 6.4 and 5.9:

- A new command line option, `-y`, has been added. This option can be used to print file descriptor paths.
- A new command line option, `-P`, has been added. This option can be used to filter system calls based on the file descriptor paths.
- A new command line option, `-I`, has been added. This option can be used to control how interactive `strace` is.
- A new command line utility, `strace-log-merge`, has been added. This utility can be used to merge timestamped `strace` output into a single file.
- The `strace` utility now uses optimized interfaces to extract data from the traced process for better performance.
- The `strace` utility now provides improved support for decoding of arguments for various system calls. In addition, a number of new system calls are supported.

### A.8. Changes in SystemTap

Red Hat Developer Toolset 2.0 is distributed with SystemTap 2.1, which provides a number of bug fixes and feature enhancements over the Red Hat Enterprise Linux system version and the version included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of new features in this release.

#### A.8.1. Changes Since Red Hat Developer Toolset 1.1

The following features have been added since the release of SystemTap included in Red Hat Developer Toolset 1.1:

- SystemTap has been updated to provide experimental support for Dyninst-based probing in the user space. Users can now execute the `stap` utility with the `--dyninst` command line option to instrument their own programs without the need to acquire root privileges.
- SystemTap is now distributed with a number of manual pages that provide a detailed explanation of common errors:
  - The `error::buildid(7stap)` manual page documents build-id verification failures.
  - The `error::dwarf(7stap)` manual page documents common DWARF debuginfo quality problems.
  - The `error::fault(7stap)` manual page documents memory access faults.
  - The `error::inode-uprobes(7stap)` manual page documents current limitations of inode-uprobes.
The **error::pass1**(7stap) manual page documents pass 1 (parsing) errors.

The **error::pass2**(7stap) manual page documents pass 2 (elaboration) errors.

The **error::pass3**(7stap) manual page documents pass 3 (translation) errors.

The **error::pass4**(7stap) manual page documents pass 4 (compilation) errors.

The **error::pass5**(7stap) manual page documents pass 5 (execution) errors.

The **error::process-tracking**(7stap) manual page documents user-space process tracking errors.

The **error::reporting**(7stap) manual page documents how to report SystemTap bugs.

- The scripting language used by SystemTap now supports the =~ operator. Users can use this operator to match regular expressions.
- The preprocessor used by the stap utility now supports an experimental macro facility. Users can use the following construct to define new macros:

  ```
  @define name(parameter...) %( body %)
  ```

  Refer to the **PREPROCESSOR MACROS** section of the stap**(1)** manual page for more information on how to use this feature.

- The backtrace-related tapset functions have been improved and standardized.

### A.9. Changes in OProfile

Red Hat Developer Toolset 2.0 is distributed with OProfile **0.9.8**, which provides a number of bug fixes and feature enhancements over the Red Hat Enterprise Linux system version and the version included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of new features in this release.

#### A.9.1. Changes Since Red Hat Developer Toolset 1.1

The following features have been added since the release of OProfile included in Red Hat Developer Toolset 1.1:

- A new command line utility, **operf**, has been added. This utility can be executed by a non-**root** user and can be used to collect profiling data.

  **Important**

  The **operf** utility relies on a kernel feature that is currently not available in Red Hat Enterprise Linux 5. Consequently, this utility only works and is supported on Red Hat Enterprise Linux 6.

- OProfile now supports Intel processors code-named Ivy Bridge.

#### A.9.2. Changes Since Red Hat Enterprise Linux 5.9

The following features have been added since the release of OProfile included in Red Hat Enterprise Linux 5.9:

- OProfile now supports AMD family11h, family12h, family14h, and AMD family15h processors.
- Generation of XML output has been corrected.
- Handling of the **--session-dir** command line option has been improved and a possible buffer
overflow in the XML generator has been fixed.

A.10. Changes in Valgrind

Red Hat Developer Toolset 2.0 is distributed with Valgrind 3.8.1, which provides a number of bug fixes over the version included in Red Hat Developer Toolset 1.1. Below is a comprehensive list of changes in this release.

A.10.1. Changes Since Red Hat Developer Toolset 1.1

The following features have been added since the release of Valgrind included in Red Hat Developer Toolset 1.1:

- The DWARF debug information for Valgrind is now distributed in a separate package, devtoolset-2-valgrind-debuginfo.
- The SGCHECK OPTIONS section of the valgrind(1) manual page has been corrected and no longer includes the BBV options. As well, the BBV options are now listed in a separate section.

A.10.2. Changes Since Red Hat Enterprise Linux 5.9

In addition to the above changes, the following features have been added since the release of Valgrind 3.5.0 included in Red Hat Enterprise Linux 5.9:

- When running in 64-bit mode, Valgrind now supports the SSE4.2 instruction set with the exception of SSE4.2 AES instructions. In 32-bit mode, Valgrind only provides support up to and including the SSSE3 instruction set.
- A new processing script cg_diff has been added to Cachegrind. This processing script can find the difference between two profiles, and can therefore be used to evaluate the performance effects of a change in a program.
- The behavior of the cg_annotate’s rarely-used --threshold option has been changed.
- Callgrind now supports branch prediction simulation and can optionally count the number of executed global bus events. Note that in order to use this functionality for a better approximation of a “Cycle Estimation” as a derived event, you must manually update the event formula in KCachegrind.
- To accommodate machines with three levels of caches, both Cachegrind and Callgrind now refer to the LL (last-level) cache rather than the L2 cache. When Cachegrind or Callgrind auto-detects the cache configuration of such a machine, it now runs the simulation as if the L2 cache is not present. Consequently, the results are less likely to match the true result for the machine and should not be considered authoritative, but provide a general idea about a program's locality.
- A new command line option --pages-as-heap has been added to Massif. When this option is enabled, Massif tracks memory allocations at the level of memory pages (as mapped by mmap, brk and similar functions) instead of tracking allocations at the level of heap blocks (as allocated with malloc, new, or new[]). Each mapped page is treated as its own block. Interpreting the page-level output is harder than the heap-level output, but allows you to account for every byte of memory used by a program. By default, the --pages-as-heap option is disabled.
- New command line options --free-is-write and --trace-alloc have been added to DRD. The --free-is-write option allows you to detect reading from already freed memory, the --trace-alloc can be used to trace of all memory allocations and deallocations.
- A number of new allocations have been added to DRD. As well, you can now annotate custom barrier implementations and benign races on static variables.
- DRD’s happens before and happens after annotations have been enhanced and can be used to annotate, for example, a smart pointer implementation.
- Helgrind’s annotation set has been significantly improved to provide a general set of annotations to
describe locks, semaphores, barriers, and condition variables. In addition, Helgrind now supports annotations to describe thread-safe reference counted heap objects.

- A new command line option `--show-possibly-lost` has been added to Memcheck. By default this option is enabled and causes the leak detector to show possibly-lost blocks.

- A new experimental heap profiler, DHAT (Dynamic Heap Analysis Tool), has been added. DHAT keeps track of allocated heap blocks, and also inspects every memory reference to see which block (if any) is being accessed. This gives a lot of insight into block lifetimes, utilization, turnover, liveness, and the location of hot and cold fields. You can use DHAT to do hot-field profiling.

- Support for unfriendly self-modifying code has been improved, and the extra overhead incurred by `--smc-check=all` has been reduced by approximately a factor of 5 as compared with the previous version of Valgrind.

- A new command line option `--fullpath-after` has been added. This option can be used to display directory names for source files in error messages, and is combined with a flexible mechanism for specifying which parts of the paths should be shown.

- A new command line option `--require-text-symbol` has been added. This option stops the execution if a specified symbol is not found in a given shared object when loaded into the process. As a result, working with function intercepting and wrapping is now safer and more reliable.

- Valgrind now implements more reliable stack unwinding on amd64-linux, particularly in the presence of function wrappers, and with gcc-4.5 compiled code.

- Valgrind now implements modest scalability (performance improvements) for very large, long-running applications.

- Valgrind now provides improved support for analyzing programs that are running in Wine. Users can now include the `valgrind/valgrind.h`, `valgrind/memcheck.h`, and `valgrind/drd.h` header files in Windows programs that are compiled with MinGW or one of the Microsoft Visual Studio compilers.
Revision History

Revision 1.0-2          Tue 10 Sep 2013          Jaromír Hradílek
Red Hat Developer Toolset 2.0 GA release of the User Guide.

Revision 1.0-1          Tue 06 Aug 2013          Jaromír Hradílek
Red Hat Developer Toolset 2.0 Beta-2 release of the User Guide.

Revision 1.0-0          Tue 28 May 2013           Jaromír Hradílek
Red Hat Developer Toolset 2.0 Beta-1 release of the User Guide.

Index

A

ABI
- compatibility, ABI Compatibility

addr2line
- features, New Features
- overview, binutils
- usage, Using Other Binary Tools

application binary interface (see ABI)

ar
- overview, binutils
- usage, Using Other Binary Tools

as (see GNU assembler)
assembling (see GNU assembler)

B

bfd
- features, New Features

binutils
- documentation, Additional Resources
- features, Main Features
- installation, Installing binutils
- overview, binutils
- usage, Using the GNU Assembler, Using the GNU Linker, Using Other Binary Tools
- version, About Red Hat Developer Toolset, binutils

C

C programming language
- compiling, Using the C Compiler, Preparing a Program for Debugging
- running, Running a C Program
- support, GNU C Compiler

C++ programming language
- compiling, Using the C++ Compiler, Preparing a Program for Debugging
- running, Running a C++ Program
- support, GNU C++ Compiler

C++11 (see GNU Compiler Collection)
c++filt
- overview, binutils
- usage, Using Other Binary Tools

C11 (see GNU Compiler Collection)
Cacheigrind
- overview, Valgrind
- usage, Using Valgrind

Callgrind
- overview, Valgrind
- usage, Using Valgrind

compatibility
- GNU Compiler Collection, Language Compatibility, Compatibility Changes, Fortran 2003 Compatibility, Fortran 2008 Compatibility, Fortran 77 Compatibility, ABI Compatibility, Debugging Compatibility, Other Compatibility
- Red Hat Developer Toolset, Compatibility

compiling (see GNU Compiler Collection)
Customer Portal
- Connect menu, The Connect Menu
- Deploy menu, The Deploy Menu
- overview, Accessing the Customer Portal
- Plain menu, The Plan Menu

D

debugging (see GNU Debugger)
Developer Toolset (see Red Hat Developer Toolset)
documentation
- Red Hat Product Documentation, Accessing Red Hat Product Documentation

DRD
- overview, Valgrind
- usage, Using Valgrind

dwp
- overview, binutils
- usage, Using Other Binary Tools

dwz
- documentation, Additional Resources
- installation, Installing dwz
- overview, dwz
- usage, Using dwz
- version, About Red Hat Developer Toolset, dwz

Dyninst
- documentation, Additional Resources
- installation, Installing Dyninst
- overview, Dyninst
- usage, Using Dyninst
- version, About Red Hat Developer Toolset, Dyninst

Eclipse
- configuration, Using the Red Hat Enterprise Linux Toolchain
- documentation, Additional Resources
- installation, Installing Eclipse
- overview, Eclipse
- usage, Using Eclipse
- version, About Red Hat Developer Toolset, Eclipse

elfedit
- features, New Features
- overview, binutils
- usage, Using Other Binary Tools

elfutils
- documentation, Additional Resources
- installation, Installing elfutils
- overview, elfutils
- usage, Using elfutils
- version, About Red Hat Developer Toolset, elfutils

eu-addr2line
- features, Changes Since Red Hat Enterprise Linux 5.9
- overview, elfutils
- usage, Using elfutils
eu-strings
- overview, elfutils
- usage, Using elfutils

eu-strip
- features, Changes Since Red Hat Enterprise Linux 6.4, Changes Since Red Hat Enterprise Linux 5.9
- overview, elfutils
- usage, Using elfutils

eu-unstrip
- overview, elfutils
- usage, Using elfutils

Feedback
- contact information for this manual, We Need Feedback

Fortran programming language
- compiling, Using the Fortran Compiler
- running, Running a Fortran Program
- support, GNU Fortran Compiler

G

g++ (see GNU Compiler Collection)
GAS (see GNU assembler)
GCC (see GNU Compiler Collection)
gcc (see GNU Compiler Collection)
GDB (see GNU Debugger)
gfortran (see GNU Compiler Collection)
Global Support Services
- contacting, Contacting Global Support Services

GNU assembler
- documentation, Additional Resources
- installation, Installing binutils
- overview, binutils
- usage, Using the GNU Assembler
GNU Compiler Collection
- C support, GNU C Compiler
- C++ support, GNU C++ Compiler
- compatibility, Language Compatibility, Compatibility Changes, Fortran 2003 Compatibility, Fortran 2008 Compatibility, Fortran 77 Compatibility, ABI Compatibility, Debugging Compatibility, Other Compatibility
- documentation, Additional Resources
- features, Main Features, Status and Features, New Features, Fortran 2003 Features, Fortran 2008 Features
- Fortran support, GNU Fortran Compiler
- installation, Installing the C Compiler, Installing the C++ Compiler, Installing the Fortran Compiler
- overview, GNU Compiler Collection (GCC)
- usage, Using the C Compiler, Using the C++ Compiler, Using the Fortran Compiler, Preparing a Program for Debugging
- version, About Red Hat Developer Toolset, GNU Compiler Collection (GCC)

GNU Debugger
- documentation, Additional Resources
- features, Main Features
- installation, Installing the GNU Debugger
- overview, GNU Debugger (GDB)
- preparation, Preparing a Program for Debugging
- usage, Running the GNU Debugger, Listing Source Code, Setting Breakpoints, Starting Execution, Displaying Current Values, Continuing Execution
- version, About Red Hat Developer Toolset, GNU Debugger (GDB)

GNU linker
- documentation, Additional Resources
- installation, Installing binutils
- overview, binutils
- usage, Using the GNU Linker

gprof
- features, New Features
- overview, binutils
- usage, Using Other Binary Tools

GSS (see Global Support Services)

Helgrind
- overview, Valgrind
- usage, Using Valgrind

help
- accessing the Customer Portal, Accessing the Customer Portal
- getting help, Do You Need Help?
- Global Support Services, Contacting Global Support Services
- Red Hat Product Documentation, Accessing Red Hat Product Documentation

L

Id (see GNU linker)

linking (see GNU linker)

M

Massif
- overview, Valgrind
- usage, Using Valgrind

Memcheck
- overview, Valgrind
- usage, Using Valgrind

memstomp
- documentation, Additional Resources
- installation, Installing memstomp
- overview, memstomp
- usage, Using memstomp
- version, About Red Hat Developer Toolset

N

nm
- overview, binutils
- usage, Using Other Binary Tools

O

objcopy
- features, New Features
- overview, binutils
- usage, Using Other Binary Tools

objdump
- features, New Features
- overview, binutils
- usage, Using Other Binary Tools

opannotate
- overview, OProfile
- usage, Using OProfile

oparchive
- overview, OProfile
- usage, Using OProfile

opcontrol
- overview, OProfile
- usage, Using OProfile

opgprof
- overview, OProfile
- usage, Using OProfile

ophelp
- overview, OProfile
- usage, Using OProfile

opimport
- overview, OProfile
- usage, Using OProfile

opjitconv
- overview, OProfile
- usage, Using OProfile

opreport
- overview, OProfile
- usage, Using OProfile

OProfile
- documentation, Additional Resources
- installation, Installing OProfile
- overview, OProfile
- usage, Using OProfile
- version, About Red Hat Developer Toolset, OProfile

oprofiled
- overview, OProfile
- usage, Using OProfile
ranlib
- overview, [binutils](#)
- usage, [Using Other Binary Tools](#)

readelf
- features, [New Features](#)
- overview, [binutils](#)
- usage, [Using Other Binary Tools](#)

Red Hat Customer Portal (see Customer Portal)

Red Hat Developer Toolset
- compatibility, [Compatibility](#)
- documentation, [Additional Resources](#), [Accessing Red Hat Product Documentation](#)

S

scl (see Software Collections)

size
- overview, [binutils](#)
- usage, [Using Other Binary Tools](#)

Software Collections
- documentation, [Additional Resources](#), [Accessing Red Hat Product Documentation](#)
- overview, [About Red Hat Developer Toolset](#)

stap
- overview, [SystemTap](#)
- usage, [Using SystemTap](#), [Using Dyninst with SystemTap](#)
stapmerge
- overview, SystemTap
- usage, Using SystemTap

stap-prep
- overview, SystemTap
- usage, Installing SystemTap

stap-report
- overview, SystemTap
- usage, Using SystemTap

staprun
- overview, SystemTap
- usage, Using SystemTap

stapsh
- overview, SystemTap
- usage, Using SystemTap

strace
- documentation, Additional Resources
- installation, Installing strace
- overview, strace
- usage, Using strace
- version, About Red Hat Developer Toolset, strace

strings
- overview, binutils
- usage, Using Other Binary Tools

strip
- overview, binutils
- usage, Using Other Binary Tools

support
- Red Hat Developer Toolset, About Red Hat Developer Toolset

SystemTap
- documentation, Additional Resources
- installation, Installing SystemTap
- overview, SystemTap
- usage, Using SystemTap, Using Dyninst with SystemTap
- version, About Red Hat Developer Toolset, SystemTap

V

Valgrind
- documentation, Additional Resources
- installation, Installing Valgrind
- overview, Valgrind
- usage, Using Valgrind
- version, About Red Hat Developer Toolset, Valgrind

version
- version, memstomp
