Abstract

The Release Notes provide high-level coverage of the improvements and additions that have been implemented in Red Hat Enterprise Linux 8.6 and document known problems in this release, as well as notable bug fixes, Technology Previews, deprecated functionality, and other details.

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better. To do so:

- For simple comments on specific passages, make sure you are viewing the documentation in the Multi-page HTML format. Highlight the part of text that you want to comment on. Then, click the Add Feedback pop-up that appears below the highlighted text, and follow the displayed instructions.

- For submitting more complex feedback, create a Bugzilla ticket:
  1. Go to the Bugzilla website.
  2. As the Component, use Documentation.
  3. Fill in the Description field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
  4. Click Submit Bug.
1. MAJOR CHANGES IN RHEL 8.6

Security
In RHEL 8.6, SELinux, the fapolicyd framework, and Policy-Based Decryption (PBD) for automated unlocking of LUKS-encrypted drives support the SAP HANA database management system. See the Red Hat Enterprise Linux Security Hardening Guide for SAP HANA 2.0 Knowledgebase article for more information.

Packages for fapolicyd have been upgraded to the upstream version 1.1. Among other improvements, you can now use the new rules.d/ and trust.d/ directories, the fagenrules script, and new options for the fapolicyd-cli command.

OpenSSH servers now support drop-in configuration files.

The pcsc-lite packages have been rebased to upstream version 1.9.5, which provides many enhancements and bug fixes.

You can now verify the versions of installed SELinux policy modules with the newly added --checksum option to the semodule command.

The SCAP Security Guide (SSG) packages have been rebased to upstream version 0.1.60, and the OpenSCAP packages have been rebased to upstream version 1.3.6.

See New features - Security for more information.

Dynamic programming languages, web and database servers
Later versions of the following components are now available as new module streams:

- PHP 8.0
- Perl 5.32

See New features - Dynamic programming languages, web and database servers for more information.

Compilers and development tools
Updated compiler toolsets
The following compiler toolsets have been updated:

- GCC Toolset 11
- LLVM Toolset 13.0.1
- Rust Toolset 1.58.1
- Go Toolset 1.17.7

See New features - Compilers and development tools for more information.

Java implementations in RHEL 8
The RHEL 8 AppStream repository includes:

- The java-17-openjdk packages, which provide the OpenJDK 17 Java Runtime Environment and the OpenJDK 17 Java Software Development Kit.
The **java-11-openjdk** packages, which provide the OpenJDK 11 Java Runtime Environment and the OpenJDK 11 Java Software Development Kit.

The **java-1.8.0-openjdk** packages, which provide the OpenJDK 8 Java Runtime Environment and the OpenJDK 8 Java Software Development Kit.

For more information, see [OpenJDK documentation](#).

**Java tools**  
RHEL 8.6 introduces a new **log4j:2** module, which contains **Apache Log4j 2**, which is a Java logging utility and a library enabling you to output log statements to a variety of output targets.

For more information, see [New features - Compilers and development tools](#). information.

**Identity Management**  
The **ansible-freeipa** roles and modules are now available in the Ansible Automation Hub, which provides fast updates of the **ansible-freeipa** content.

### 1.2. IN-PLACE UPGRADE AND OS CONVERSION

**In-place upgrade from RHEL 7 to RHEL 8**  
The supported in-place upgrade paths currently are:

- From RHEL 7.9 to RHEL 8.4 and RHEL 8.6 on the 64-bit Intel, IBM POWER 8 (little endian), and IBM Z architectures
- From RHEL 7.6 to RHEL 8.4 on architectures that require kernel version 4.14: IBM POWER 9 (little endian) and IBM Z (Structure A). This is the final in-place upgrade path for these architectures.
- From RHEL 7.9 to RHEL 8.2 and RHEL 8.6 on systems with SAP HANA on the 64-bit Intel architecture. To ensure your system with SAP HANA remains supported after upgrading to RHEL 8.2, enable the RHEL 8.2 Update Services for SAP Solutions (E4S) repositories.

For more information, see [Supported in-place upgrade paths for Red Hat Enterprise Linux](#). For instructions on performing an in-place upgrade, see [Upgrading from RHEL 7 to RHEL 8](#). For instructions on performing an in-place upgrade on systems with SAP environments, see [How to in-place upgrade SAP environments from RHEL 7 to RHEL 8](#).

Notable enhancements include:

- With the release of RHEL 8.6, multiple upgrade paths are now available for the in-place upgrade from RHEL 7 to RHEL 8. This allows you to decide which RHEL 8 minor version you want to upgrade your system to instead of upgrading to the latest RHEL 8 minor version by default. Note that the available upgrade paths differ between RHEL systems and RHEL systems with SAP HANA.

- The **Leapp** utility now runs significantly faster during the pre-upgrade and the initial stages of the in-place upgrade.

- The in-place upgrade is also supported for SAP hosting systems for the following cloud image types:
  - Bring-your-own-subscription (BYOS) systems on any public cloud platform which uses Red Hat Subscription Manager (RHSM) for a RHEL subscription.
- Pay-as-you-go (PAYG) instances on Amazon Web Services (AWS) and Microsoft Azure with Red Hat Update Infrastructure (RHUI).

**In-place upgrade from RHEL 6 to RHEL 8**

To upgrade from RHEL 6.10 to RHEL 8, follow instructions in Upgrading from RHEL 6 to RHEL 8.

**Conversion from a different Linux distribution to RHEL**

If you are using CentOS Linux 8 or Oracle Linux 8, you can convert your operating system to RHEL 8 using the Red Hat-supported Convert2RHEL utility. For more information, see Converting from an RPM-based Linux distribution to RHEL.

If you are using an earlier version of CentOS Linux or Oracle Linux, namely versions 6 or 7, you can convert your operating system to RHEL and then perform an in-place upgrade to RHEL 8. Note that CentOS Linux 6 and Oracle Linux 6 conversions use the unsupported Convert2RHEL utility. For more information on unsupported conversions, see How to perform an unsupported conversion from a RHEL-derived Linux distribution to RHEL.

For information regarding how Red Hat supports conversions from other Linux distributions to RHEL, see the Convert2RHEL Support Policy document.

### 1.3. RED HAT CUSTOMER PORTAL LABS

**Red Hat Customer Portal Labs** is a set of tools in a section of the Customer Portal available at https://access.redhat.com/labs/. The applications in Red Hat Customer Portal Labs can help you improve performance, quickly troubleshoot issues, identify security problems, and quickly deploy and configure complex applications. Some of the most popular applications are:

- Registration Assistant
- Product Life Cycle Checker
- Kickstart Generator
- Kickstart Converter
- Red Hat Enterprise Linux Upgrade Helper
- Red Hat Satellite Upgrade Helper
- Red Hat Code Browser
- JVM Options Configuration Tool
- Red Hat CVE Checker
- Red Hat Product Certificates
- Load Balancer Configuration Tool
- Yum Repository Configuration Helper
- Red Hat Memory Analyzer
- Kernel Oops Analyzer
- Red Hat Product Errata Advisory Checker
1.4. ADDITIONAL RESOURCES

- **Capabilities and limits** of Red Hat Enterprise Linux 8 as compared to other versions of the system are available in the Knowledgebase article [Red Hat Enterprise Linux technology capabilities and limits](#).

- Information regarding the Red Hat Enterprise Linux life cycle is provided in the [Red Hat Enterprise Linux Life Cycle](#) document.

- The Package manifest document provides a **package listing** for RHEL 8.

- Major **differences between RHEL 7 and RHEL 8** including removed functionality, are documented in [Considerations in adopting RHEL 8](#).

- Instructions on how to perform an **in-place upgrade from RHEL 7 to RHEL 8** are provided by the document [Upgrading from RHEL 7 to RHEL 8](#).

- The **Red Hat Insights** service, which enables you to proactively identify, examine, and resolve known technical issues, is now available with all RHEL subscriptions. For instructions on how to install the Red Hat Insights client and register your system to the service, see the [Red Hat Insights Get Started](#) page.
CHAPTER 2. ARCHITECTURES

Red Hat Enterprise Linux 8.6 is distributed with the kernel version 4.18.0-372, which provides support for the following architectures:

- AMD and Intel 64-bit architectures
- The 64-bit ARM architecture
- IBM Power Systems, Little Endian
- 64-bit IBM Z

Make sure you purchase the appropriate subscription for each architecture. For more information, see Get Started with Red Hat Enterprise Linux - additional architectures. For a list of available subscriptions, see Subscription Utilization on the Customer Portal.
CHAPTER 3. DISTRIBUTION OF CONTENT IN RHEL 8

3.1. INSTALLATION

Red Hat Enterprise Linux 8 is installed using ISO images. Two types of ISO image are available for the AMD64, Intel 64-bit, 64-bit ARM, IBM Power Systems, and IBM Z architectures:

- Binary DVD ISO: A full installation image that contains the BaseOS and AppStream repositories and allows you to complete the installation without additional repositories.

  **NOTE**
  The Binary DVD ISO image is larger than 4.7 GB, and as a result, it might not fit on a single-layer DVD. A dual-layer DVD or USB key is recommended when using the Binary DVD ISO image to create bootable installation media. You can also use the Image Builder tool to create customized RHEL images. For more information about Image Builder, see the *Composing a customized RHEL system image* document.

- Boot ISO: A minimal boot ISO image that is used to boot into the installation program. This option requires access to the BaseOS and AppStream repositories to install software packages. The repositories are part of the Binary DVD ISO image.

See the *Performing a standard RHEL installation* document for instructions on downloading ISO images, creating installation media, and completing a RHEL installation. For automated Kickstart installations and other advanced topics, see the *Performing an advanced RHEL installation* document.

3.2. REPOSITORIES

Red Hat Enterprise Linux 8 is distributed through two main repositories:

- BaseOS
- AppStream

Both repositories are required for a basic RHEL installation, and are available with all RHEL subscriptions.

Content in the BaseOS repository is intended to provide the core set of the underlying OS functionality that provides the foundation for all installations. This content is available in the RPM format and is subject to support terms similar to those in previous releases of RHEL. For a list of packages distributed through BaseOS, see the *Package manifest*.

Content in the Application Stream repository includes additional user space applications, runtime languages, and databases in support of the varied workloads and use cases. Application Streams are available in the familiar RPM format, as an extension to the RPM format called *modules*, or as Software Collections. For a list of packages available in AppStream, see the *Package manifest*.

In addition, the CodeReady Linux Builder repository is available with all RHEL subscriptions. It provides additional packages for use by developers. Packages included in the CodeReady Linux Builder repository are unsupported.

For more information about RHEL 8 repositories, see the *Package manifest*.
3.3. APPLICATION STREAMS

Red Hat Enterprise Linux 8 introduces the concept of Application Streams. Multiple versions of user space components are now delivered and updated more frequently than the core operating system packages. This provides greater flexibility to customize Red Hat Enterprise Linux without impacting the underlying stability of the platform or specific deployments.

Components made available as Application Streams can be packaged as modules or RPM packages and are delivered through the AppStream repository in RHEL 8. Each Application Stream component has a given life cycle, either the same as RHEL 8 or shorter. For details, see Red Hat Enterprise Linux Life Cycle.

Modules are collections of packages representing a logical unit: an application, a language stack, a database, or a set of tools. These packages are built, tested, and released together.

Module streams represent versions of the Application Stream components. For example, several streams (versions) of the PostgreSQL database server are available in the postgresql module with the default postgresql:10 stream. Only one module stream can be installed on the system. Different versions can be used in separate containers.

Detailed module commands are described in the Installing, managing, and removing user-space components document. For a list of modules available in AppStream, see the Package manifest.

3.4. PACKAGE MANAGEMENT WITH YUM/DNF

On Red Hat Enterprise Linux 8, installing software is ensured by the YUM tool, which is based on the DNF technology. We deliberately adhere to usage of the yum term for consistency with previous major versions of RHEL. However, if you type dnf instead of yum, the command works as expected because yum is an alias to dnf for compatibility.

For more details, see the following documentation:

- Installing, managing, and removing user-space components
- Considerations in adopting RHEL 8
CHAPTER 4. NEW FEATURES

This part describes new features and major enhancements introduced in Red Hat Enterprise Linux 8.6.

4.1. INSTALLER AND IMAGE CREATION

Image Builder now supports cross-version image building

With this enhancement, you can use Image Builder to create images of multiple RHEL minor releases that are different from the host, such as RHEL 8.4 and RHEL 8.5. As a result, you can avoid maintaining multiple Image Builder instances.

(BZ#2019003)

Image Builder supports customized file system partition on LVM

With this enhancement, if you have more than one partition, you can create images with a customized file system partition on LVM and resize those partitions at runtime. For that, you can specify a customized filesystem configuration in your blueprint and then create images with the desired disk layout. The default filesystem layout remains unchanged - if you use plain images without file system customization, the root partition is resized by cloud-init.

(JIRA:RHELPLAN-102505)

4.2. RHEL FOR EDGE

Support for automatic provisioning and onboarding RHEL for Edge images

Previously, to configure a new device at a location, it required installing the system and performing initial configuration manually. With this update, you can build a RHEL for Edge Simplified Installer image, provision it to a RHEL for Edge image, and use the FDO (FIDO device onboarding) process to automatically provision and onboard your Edge devices, exchange data with other devices and systems connected on the networks. As a result, the FIDO device onboarding protocol performs device initialization at the manufacturing stage and then late binding to actually use the device.

(BZ#1989930)

RHEL for Edge now supports Greenboot built-in health checks by default

With this update, RHEL for Edge Greenboot now includes built-in health checks with watchdog feature to ensure that the hardware does not hang or freeze while rebooting. With that, you can benefit from the following features:

- It makes it simple for watchdogs hardware users to adopt the built-in health checks
- A set of default health checks that provide value for built-in OS components
- The watchdog is now present as default presets, which makes it easy to enable or disable this feature
- Ability to create custom health checks based on the already available health checks.

(BZ#2083036)

RHEL 8 rebased to rpm-ostree v2022.2
RHEL 8 is distributed with the rpm-ostree version v2022.2, which provides multiple bug fixes and enhancements. Notable changes include:

- Kernel arguments can now be updated in an idempotent way, by using the new `--append-if-missing` and `--delete-if-present` kargs flags.

- The Count Me feature from YUM is now fully disabled by default in all repo queries and will only be triggered by the corresponding `rpm-ostree-countme.timer` and `rpm-ostree-countme.service` units. See `countme`.

- The post-processing logic can now process the `user.ima` IMA extended attribute. When an `xattr` extended attribute is found, the system automatically translates it to `security.ima` in the final OSTree package content.

- The `treefile` file has a new `repo-packages` field. You can use it to pin a set of packages to a specific repository.

- Ability to use modularity on the compose and client side.

- Container images are now used as a compose target and also as an upgrade source.

(BZ#2032594)

### 4.3. SUBSCRIPTION MANAGEMENT

**Merged system purpose commands under subscription-manager syspurpose**

Previously, there were multiple subscription-manager modules (`addons`, `role`, `service-level`, and `usage`) for setting attributes related to system purpose. These modules have been moved under the new `subscription-manager syspurpose` module.

The original subscription-manager modules (`addons`, `role`, `service-level`, and `usage`) are now deprecated. Additionally, the package (`python3-syspurpose`) that provides the `syspurpose` command line tool has been deprecated in RHEL 8.6. All the capabilities of this package are covered by the new `subscription-manager syspurpose` module.

This update provides a consistent way to view, set, and update all system purpose attributes using a single command of subscription-manager; this replaces all the existing system purpose commands with their equivalent versions available as a new subcommand. For example, `subscription-manager role --set SystemRole` becomes `subscription-manager syspurpose role --set SystemRole` and so on.

For complete information about the new commands, options, and other attributes, see the `SYSPURPOSE OPTIONS` section in the `subscription-manager` man page.

(BZ#2000883)

### 4.4. SOFTWARE MANAGEMENT

**The modulesync command is now available to replace certain workflows in RHEL 8**

In Red Hat Enterprise Linux 8, modular packages cannot be installed without modular metadata. Previously, you could use the `yum` command to download packages, and then use the `createrepo_c` command to redistribute those packages.
This enhancement introduces the `modulesync` command to ensure the presence of modular metadata, which ensures package installability. This command downloads `rpm` packages from modules and creates a repository with modular metadata in a working directory.

(BZ#1868047)

A new `--path` CLI option is added to RPM

With this update, you can query packages by a file that is currently not installed using a new `--path` CLI option. This option is similar to the existing `--file` option, but matches packages solely based on the provided path. Note that the file at that path does not need to exist on disk.

The `--path` CLI option can be useful when a user excludes all documentation files at install time by using the `--nodocs` option with `yum`. In this case, by using the `--path` option, you can display the owning package of such an excluded file, whereas the `--file` option will not display the package because the requested file does not exist.

(BZ#1940895)

4.5. SHELLS AND COMMAND-LINE TOOLS

The `lsvpd` package rebased to version 1.7.13

The `lsvpd` package has been rebased to version 1.7.13. Notable bug fixes and enhancements include:

- Added support for SCSI location code.
- Fixed length of absolute path `getDevTreePath` in `sysfstreecollector`.

(BZ#1993557)

The `net-snmp-cert gencert` tool now uses the SHA512 encryption algorithm instead of SHA1

In order to increase security, the `net-snmp-cert gencert` tool has been updated to generate certificates using SHA512 encryption algorithm by default.

(BZ#1908331)

The `dnn` and `text` modules are available in the `opencv` package

The `dnn` module containing Deep Neural Networks for image classification inference and the `text` module for scene text detection and recognition are now available in the `opencv` package.

(BZ#2007780)

The `powerpc-utils` package rebased to version 1.3.9

The `powerpc-utils` package has been upgraded to version 1.3.9. Notable bug fixes, and enhancements include:

- Increased log size to 1MB in `drmgr`.
- Fixed checking `HCNID` array size at boot time.
- Implemented `autoconnect-slaves` on HNV connections in `hcnmgr`.
- Improved the HNV bond list connections in `hcnmgr`.
- Uses `hexdump` from `util-linux` instead of `xxd` from `vim` in `hcncmgr`.

- The `hcnc-init.service` starts together with NetworkManager.

- Fixed OF to logical FC lookup for multipath in `ofpathname`.

- Fixed OF to logical lookup with partitions in `ofpathname`.

- Fixed bootlist for multipath devices with more than 5 paths.

- Introduced `lparnumascore` command to detect the NUMA affinity score for the running LPAR.

- Added the `-x` option in `lpartstat` to enhance security.

- Fixed `ofpathname` race with `udev` rename in `hcncmgr`.

- Fixed `qrydev` in HNV, and removed `lsdevinfo`.

(BZ#2028690)

The `powerpc-utils` package now supports vNIC as a backup device

The `powerpc-utils` package now supports Virtual Network Interface cards (vNIC) as a backup `vdevice` for Hybrid Network Virtualization (HNV).

(BZ#2022225)

The `opencryptoki` package rebased to version 3.17.0

The `opencryptoki` package has been rebased to version 3.17.0. Notable bug fixes and enhancements include:

- The `p11sak` tool offers a new function of listing keys.

- Added support for OpenSSL 3.0.

- Added support for event notifications.

- Added SW fallbacks in ICA tokens.

- The WebSphere Application Server no longer fails to start with the hardware crypto adapter enabled.

- The `opencryptoki.module` was removed, and the `p11-kit list-modules` command no longer causes error messages.

(BZ#1984993)

Certain network interfaces and IP addresses can be excluded when creating a rescue image

You can use the `EXCLUDE_IP_ADDRESSES` variable to ignore certain IP addresses, and the `EXCLUDE_NETWORK_INTERFACES` variable to ignore certain network interfaces when creating a rescue image.

On servers with floating addresses, you need to stop the ReaR rescue environment from configuring floating addresses that are moved to a fail-over server until the original server is recovered. Otherwise, a conflict with the fail-over server would occur and cause a consequent disruption of the services running

CHAPTER 4. NEW FEATURES

17
on the fail-over server. To prevent conflicts, you can perform the following actions in the ReaR configuration file `/etc/rear/local.conf`:

- exclude the IP addresses in the ReaR by providing the `EXCLUDE_IP_ADDRESSES` variable as a bash array of addresses. For example: `EXCLUDE_IP_ADDRESSES=( 192.0.2.27 192.0.2.10 )`,

- exclude the network interfaces in the ReaR by providing the `EXCLUDE_NETWORK_INTERFACES` variable as a bash array of interfaces. For example: `EXCLUDE_NETWORK_INTERFACES=( eno1d1 )`.

(BZ#2035939)

4.6. INFRASTRUCTURE SERVICES

New `bind9.16` package version 9.16.23 introduced

A new `bind9.16` package version 9.16.23 has been introduced as an alternative to `bind` component version 9.11.36. Notable enhancements include:

- Introduced new Key and Signing Policy feature in DNSSEC.
- Introduced the QNAME minimisation to improve privacy.
- Introduced the `validate-except` feature to Permanent.
- Negative Trust Anchors to temporarily disable DNSSEC validation.
- Refactored the response policy zones (RPZ).
- Introduced new naming conventions for zone types: `primary` and `secondary` zone types are used as synonyms to `master` and `slave`.
- Introduced a supplementary YAML output mode of `dig`, `mdig`, and `delv` commands.
- The `filter-aaaa` functionality was moved into separate `filter-a` and `filter-aaaa` plugins.
- Introduced a new zone type mirror support ([RFC 8806](https://tools.ietf.org/html/rfc8806)).

Removed features:

- The `dnssec-enabled` option has been removed, DNSSEC is enabled by default, and the `dnssec-enabled` keywords are no longer accepted.
- The `lwresd` lightweight resolver daemon, and `liblwres` lightweight resolver library have been removed.

(BZ#1873486)

CUPS is available as a container image

The Common Unix Printing System (CUPS) is now available as a container image, and you can deploy it from the Red Hat Container Catalog.

(BZ#1913715)

The `bind` component rebased to version 9.11.36

The `bind` component has been updated to version 9.11.36. Notable bug fixes and enhancements include:
• Improved the **lame-ttl** option to be more secure.

• A multiple threads bug affecting RBTDB instances no longer results in assertion failure in `free_rbtdb()`.

• Updated implementation of the ZONEMD RR type to match RFC 8976.

• The maximum supported number of NSEC3 iterations has been reduced to 150. Records with more iterations are treated as insecure.

• An invalid direction field in a LOC record no longer results in a failure.

  *(BZ#2013993)*

**CUPS driverless printing is available in CUPS Web UI**

CUPS driverless printing, based on the IPP Everywhere model, is available in the CUPS Web UI. In addition to the `lpadmin` command used in the CLI, you can create an IPP Everywhere queue in the CUPS Web UI to print to network printers without special software.

For more information, see link:https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html/deploying_different_types_of_servers/configuring-printing_deploying-different-types-of-servers#configuring-driverless-printing_configuring-printing

  *(BZ#2032965)*

**4.7. SECURITY**

The **pcsc-lite** packages rebased to 1.9.5

The **pcsc-lite** packages have been rebased to upstream version 1.9.5. This update provides new enhancements and bug fixes, most notably:

• The **pcscd** daemon no longer automatically exits after inactivity when started manually.

• The **pcsc-spy** utility now supports Python 3 and a new `--thread` option.

• Performance of the **SCardEndTransaction()** function has been improved.

• The **poll()** function replaced the **select()** function, which allows file descriptor numbers higher than `FD_SETSIZE`.

• Many memory leaks and concurrency problems have been fixed.

  *(BZ#2014641)*

**Crypto policies support diffie-hellman-group14-sha256**

You can now use the **diffie-hellman-group14-sha256** key exchange (KEX) algorithm for the **libssh** library in RHEL system-wide cryptographic policies. This update also provides parity with OpenSSH, which also supports this KEX algorithm. With this update, **libssh** has **diffie-hellman-group14-sha256** enabled by default, but you can disable it by using a custom crypto policy.

  *(BZ#2023744)*

**OpenSSH servers now support drop-in configuration files**
The `sshd_config` file supports the `Include` directive, which means you can include configuration files in another directory. This makes it easier to apply system-specific configurations on OpenSSH servers by using automation tools such as Ansible Engine. It is also more consistent with the capabilities of the `ssh_config` file. In addition, drop-in configuration files also make it easier to organize different configuration files for different uses, such as filter incoming connections.

(BZ#1926103)

### sshd_config:ClientAliveCountMax=0 disables connection termination

Setting the SSHD configuration option `ClientAliveCountMax` to 0 now disables connection termination. This aligns the behavior of this option with the upstream. As a consequence, OpenSSH no longer disconnects idle SSH users when it reaches the timeout configured by the `ClientAliveInterval` option.

(BZ#2015828)

### libssh rebased to 0.9.6

The `libssh` package has been rebased to upstream version 0.9.6. This version provides bug fixes and enhancements, most notably:

- Support for multiple identity files. The files are processed from the bottom to the top as listed in the `~/.ssh/config` file.
- Parsing of sub-second times in SFTP is fixed.
- A regression of the `ssh_channel_poll_timeout()` function returning `SSH_AGAIN` unexpectedly is now fixed.
- A possible heap-buffer overflow after key re-exchange is fixed.
- A handshake bug when AEAD cipher is matched but there is no HMAC overlap is fixed.
- Several memory leaks on error paths are fixed.

(BZ#1896651)

### Libreswan rebased to 4.5

Libreswan has been rebased to upstream version 4.5. This version provides many bug fixes and enhancements, most notably:

- Support of Internet Key Exchange version 2 (IKEv2) for Labeled IPsec.
- Support for childless initiation of Internet Key Exchange (IKE) Security Association (SA).

(BZ#2017352)

### New option to verify SELinux module checksums

With the newly added `--checksum` option to the `semodule` command, you can verify the versions of installed SELinux policy modules.

Because Common Intermediate Language (CIL) does not store module name and module version in the module itself, there previously was no simple way to verify that the installed module is the same version as the module which was supposed to be installed.

With the new command `semodule -l --checksum`, you receive a SHA256 hash of the specified module and can compare it with the checksum of the original file, which is faster than reinstalling modules.
OpenSCAP can read local files

OpenSCAP can now consume local files instead of remote SCAP source data stream components. Previously, you could not perform a complete evaluation of SCAP source data streams containing remote components on systems that have no internet access. On these systems, OpenSCAP could not evaluate some of the rules in these data streams because the remote components needed to be downloaded from the internet. With this update, you can download and copy the remote SCAP source data stream components to the target system before performing the OpenSCAP scan and provide them to OpenSCAP by using the --local-files option with the oscap command.

(SSG now scans and remediates rules for home directories and interactive users)

OVAL content to check and remediate all existing rules related to home directories used by interactive users was added to the SCAP Security Guide (SSG) suite. Many benchmarks require verification of properties and content usually found within home directories of interactive users. Because the existence and the number of interactive users in a system may vary, there was previously no robust solution to cover this gap using the OVAL language. This update adds OVAL checks and remediations that detect local interactive users in a system and their respective home directories. As a result, SSG can safely check and remediate all related benchmark requirements.

(SCAP rules now have a warning message to configure Audit log buffer for large systems)

The SCAP rule xccdf_org.ssgproject.content_rule_audit_basic_configuration now displays a performance warning that suggests users of large systems where the Audit log buffer configured by this rule might be too small and can override the custom value. The warning also describes the process to configure a larger Audit log buffer. With this enhancement, users of large systems can stay compliant and have their Audit log buffer set correctly.

(SSG now supports the /etc/security/faillock.conf file)

This enhancement adds support for the /etc/security/faillock.conf file in SCAP Security Guide (SSG). With this update, SSG can assess and remediate the /etc/security/faillock.conf file for definition of pam_faillock settings. The authselect tool is also used to enable the pam_faillock module while ensuring the integrity of pam files. As a result, the assessment and remediation of the pam_faillock module is aligned with the latest versions and best practices.

(SCAP Security Guide rebased to 0.1.60)

The SCAP Security Guide (SSG) packages have been rebased to upstream version 0.1.60. This version provides various enhancements and bug fixes, most notably:
Rules hardening the PAM stack now use **authselect** as the configuration tool.

Tailoring files that define profiles which represent the differences between DISA STIG automated SCAP content and SCAP automated content (delta tailoring) are now supported.

The rule `xccdf_org.ssgproject.content_enable_fips_mode` now checks only whether the FIPS mode has been enabled properly. It does not guarantee that system components have undergone FIPS certification.

(BZ#2014485)

**DISA STIG profile supports Red Hat Virtualization 4.4**

The **DISA STIG for Red Hat Enterprise Linux 8** profile version VIR5 has been enhanced to support Red Hat Virtualization 4.4. This profile aligns with the RHEL 8 Security Technical Implementation Guide (STIG) manual benchmark provided by the Defense Information Systems Agency (DISA). However, some configurations are not applied on hosts where Red Hat Virtualization (RHV) is installed because they prevent Red Hat Virtualization from installing and working properly.

When the STIG profile is applied on a Red Hat Virtualization Host (RHVH), on a self-hosted install (RHELH), or on a host with RHV Manager installed, the following rules result in 'notapplicable':

- `package_gss_proxy_removed`
- `package_krb5-workstation_removed`
- `package_tuned_removed`
- `sshd_disable_root_login`
- `sudo_remove_nopasswd`
- `sysctl_net_ipv4_ip_forward`
- `xwindows_remove_packages`

**WARNING**

Automatic remediation might render the system non-functional. Run the remediation in a test environment first.

(BZ#2021802)

**OpenSCAP rebased to 1.3.6**

The OpenSCAP packages have been rebased to upstream version 1.3.6. This version provides various bug fixes and enhancements, most notably:

- You can provide local copies of remote SCAP source data stream components by using the `--local-files` option.
- OpenSCAP accepts multiple `--rule` arguments to select multiple rules on the command line.
OpenSCAP allows skipping evaluation of some rules using the `--skip-rule` option.

You can restrict memory consumed by OpenSCAP probes by using the `OSCAP_PROBE_MEMORY_USAGE_RATIO` environment variable.

OpenSCAP now supports the OSBuild Blueprint as a remediation type. 
(BZ#2041781)

clevis-systemd no longer depends on nc

With this enhancement, the `clevis-systemd` package no longer depends on the `nc` package. The dependency did not work correctly when used with Extra Packages for Enterprise Linux (EPEL). 
(BZ#1949289)

audit rebased to 3.0.7

The `audit` packages have been upgraded to version 3.0.7 which introduces many enhancements and bug fixes. Most notably:

- Added `sudoers` to Audit base rules.
- Added the `--eoe-timeout` option to the `ausearch` command and its analogous `eoe_timeout` option to `auditd.conf` file that specifies the value for end of event timeout, which impacts how `ausearch` parses co-located events.
- Introduced a fix for the ‘audisp-remote’ plugin that used 100% of CPU capacity when the remote location was not available.
(BZ#1939406)

Audit now provides options for specifying the end of the event timeout

With this release, the `ausearch` tool supports the `--eoe-timeout` option, and the `auditd.conf` file contains the `end_of_event_timeout` option. You can use these options to specify the end of the event timeout to avoid problems with parsing co-located events. The default value for the end of the event timeout is set to two seconds. 
(BZ#1921658)

Adding sudoers to Audit base rules

With this enhancement, the `/etc/sudoers` and the `/etc/sudoers.d/` directories are added to Audit base rules such as the Payment Card Industry Data Security Standard (PCI DSS) and the Operating Systems Protection Profile (OSPP). This increases the security by monitoring configuration changes in privileged areas such as `sudoers`. 
(BZ#1927884)

Rsystlog includes the mmfields module for higher-performance operations and CEF

Rsystlog now includes the `rsyslog-mmfields` subpackage which provides the `mmfields` module. This is an alternative to using the property replacer field extraction, but in contrast to the property replacer, all fields are extracted at once and stored inside the structured data part. As a result, you can use `mmfields` particularly for processing field-based log formats, for example Common Event Format (CEF), and if you need a large number of fields or reuse specific fields. In these cases, `mmfields` has better performance than existing Rsystlog features.
libcap rebased to version 2.48

The libcap packages have been upgraded to upstream version 2.48, which provides a number of bug fixes and enhancements over the previous version, most notably:

- Helper library for POSIX semantic system calls (libpsx)
- Support for overriding system call functions
- IAB abstraction for capability sets
- Additional capsh testing features

fapolicyd rebased to 1.1

The fapolicyd packages have been upgraded to the upstream version 1.1, which contains many improvements and bug fixes. Most notable changes include the following:

- The /etc/fapolicyd/rules.d/ directory for files containing allow and deny execution rules replaces the /etc/fapolicyd/fapolicyd.rules file. The fagenrules script now merges all component rule files in this directory to the /etc/fapolicyd/compiled.rules file. See the new fagenrules(8) man page for more details.

- In addition to the /etc/fapolicyd/fapolicyd.trust file for marking files outside of the RPM database as trusted, you can now use the new /etc/fapolicyd/trust.d directory, which supports separating a list of trusted files into more files. You can also add an entry for a file by using the fapolicyd-cli -f subcommand with the --trust-file directive to these files. See the fapolicyd-cli(1) and fapolicyd.trust(13) man pages for more information.

- The fapolicyd trust database now supports white spaces in file names.

- fapolicyd now stores the correct path to an executable file when it adds the file to the trust database.

libseccomp rebased to 2.5.2

The libseccomp packages have been rebased to upstream version 2.5.2. This version provides bug fixes and enhancements, most notably:

- Updated the syscall table for Linux to version v5.14-rc7.
- Added the get_notify_fd() function to the Python bindings to get the notification file descriptor.
- Consolidated multiplexed syscall handling for all architectures into one location.
- Added multiplexed syscall support to the PowerPC (PPC) and MIPS architectures.
- Changed the meaning of the SECCOMP_IOCTL_NOTIF_ID_VALID operation within the kernel.
- Changed the libseccomp file descriptor notification logic to support the kernel’s previous and new usage of SECCOMP_IOCTL_NOTIF_ID_VALID.
4.8. NETWORKING

CleanUpModulesOnExit firewalld global configuration option is now available

Previously, when restarting or otherwise shutting down firewalld, firewalld recursively unloaded kernel modules. As a result, other packages attempting to use these modules or dependent modules would fail. With this upgrade, users can set the CleanUpModulesOnExit option to no to stop firewalld from unloading these kernel modules.

(BZ#1980206)

Restoring large nftables sets requires less memory

With this enhancement, the nftables framework requires significantly less memory when you restore large sets. The algorithm which prepares the netlink message has been improved, and, as a result, restoring a set can use up to 40% less memory.

(BZ#2047821)

The nmstate API now supports OVS-DPDK

This enhancement adds the schema for the Open vSwitch (OVS) Data Plane Development Kit (DPDK) to the nmstate API. As a result, you can use nmstate to configure OVS devices with DPDK ports.

(BZ#2003976)

The nmstate API now supports VLAN and QoS ID in SR-IOV virtual functions

This update enhances the nmstate API with support for local area network (VLAN) and quality of service (QoS) in single root I/O virtualization (SR-IOV) virtual functions. As a result, you can use nmstate to configure these features.

(BZ#2004006)

NetworkManager rebased to version 1.36.0

The NetworkManager packages have been upgraded to upstream version 1.36.0, which provides a number of enhancements and bug fixes over the previous version:

- The handling of layer 3 configurations has been reworked to improve the stability, performance, and memory usage.
- NetworkManager now supports the rd.znet_ifnames kernel command line option on the IBM Z platform.
- The blackhole, unreachable, and prohibit route types have been added.
- NetworkManager now ignores routes managed by routing services.
- The Wi-Fi Protected Access version 3 (WPA3) network security has been improved by enabling the hash-to-element (H2E) method when generating simultaneous authentication of equals (SAE) password elements.
- The service now correctly handles replies from DHCP servers that send duplicate address or mask options.
• You can now turn off MAC aging on bridges.

• NetworkManager no longer listens for netlink events for traffic control objects, such as qdiscs and filters.

• Network bonds now support setting a queue ID for bond ports.

For further information about notable changes, read the upstream release notes:

• NetworkManager 1.36.0

• NetworkManager 1.34.0

(BZ#1996617)

The hostapd package has been added to RHEL 8.6

With this release, RHEL provides the hostapd package. However, Red Hat supports hostapd only to set up a RHEL host as an 802.1X authenticator in Ethernet networks. Other scenarios, such as Wi-Fi access points or authenticators in Wi-Fi networks, are not supported.

For details about configuring RHEL as an 802.1X authenticator with a FreeRADIUS back end, see Setting up an 802.1x network authentication service for LAN clients using hostapd with FreeRADIUS backend.

(BZ#2016946)

NetworkManager now supports setting the number of receiving queues (rx_queue) on OVS-DPDK interfaces

With this enhancement, you can use NetworkManager to configure the n_rxq setting of Open vSwitch (OVS) Data Plane Development Kit (DPDK) interfaces. Use the ovs-dpdk.n-rxq attribute in NetworkManager to set the number of receiving queues on OVS-DPDK interfaces.

For example, to configure 2 receiving queues in OVS interface named ovs-iface0, enter:

```
# nmcli connection modify ovs-iface0 ovs-dpdk.nrxq 2
```

(BZ#2001563)

The nftables framework now supports nft set elements with attached counters

Previously, in the netfilter framework, nftables set counters were not supported. The nftables framework is configurable by the nft tool. The kernel allows this tool to count the network packets from a given source address with a statement add @myset {ip saddr counter}. In this update, you can count packets that match a specific criteria with a dynamic set and elements with attached counters.

(BZ#1983635)

4.9. KERNEL

Kernel version in RHEL 8.6

Red Hat Enterprise Linux 8.6 is distributed with the kernel version 4.18.0-372.

See also Important changes to external kernel parameters and Device drivers.

(BZ#1839151)
Extended Berkeley Packet Filter for RHEL 8.6

The **Extended Berkeley Packet Filter (eBPF)** is an in-kernel virtual machine that allows code execution in the kernel space, in the restricted sandbox environment with access to a limited set of functions. The virtual machine executes a special assembly-like code.

The eBPF bytecode first loads to the kernel, followed by its verification, code translation to the native machine code with just-in-time compilation, and then the virtual machine executes the code.

Red Hat ships numerous components that utilize the eBPF virtual machine. Each component is in a different development phase, and thus not all components are currently fully supported. In RHEL 8.6, the following eBPF components are supported:

- **The BPF Compiler Collection (BCC) tools package**, which provides tools for I/O analysis, networking, and monitoring of Linux operating systems using eBPF.
- **The BCC library** which allows the development of tools similar to those provided in the BCC tools package.
- **The eBPF for Traffic Control (tc) feature**, which enables programmable packet processing inside the kernel network data path.
- **The bpftrace tracing language**
- **The eXpress Data Path (XDP) feature**, which provides access to received packets before the kernel networking stack processes them, is supported under specific conditions. For more information see, XDP is conditionally supported and [Overview of networking eBPF features in RHEL](#).
- **The libbpf package**, which is crucial for bpf related applications like bpftrace and bpf/xdp development.
- **The xdp-tools package**, which contains userspace support utilities for the XDP feature, is now supported on the AMD and Intel 64-bit architectures. This includes the libxdp library, the xdp-loader utility for loading XDP programs, the xdp-filter example program for packet filtering, and the xdpdump utility for capturing packets from a network interface with XDP enabled.

Note that all other eBPF components are available as Technology Preview, unless a specific component is indicated as supported.

The following notable eBPF components are currently available as Technology Preview:

- **The AF_XDP socket for connecting the eXpress Data Path (XDP) path to user space**

For more information regarding the Technology Preview components, see [eBPF available as a Technology Preview](#).

(BZ#1780124)

The osnoise and timerlat tracers were added in RHEL 8

The **osnoise** tracer measures operating system noise. That is, the interruptions of applications by the OS and hardware interrupts. It also provides a set of tracepoints to help find the source of the OS noise. The **timerlat** tracer measures the wakeup latencies and helps to identify the causes of such latencies of real-time (RT) threads. In RT computing, latency is absolutely crucial and even a minimal delay can be detrimental. The osnoise and timerlat tracers enable you to investigate and find causes of OS interference with applications and wakeup delay of RT threads.
The strace utility can now display mismatches between the actual SELinux contexts and the definitions extracted from the SELinux context database.

An existing `--secontext` option of strace has been extended with the `mismatch` parameter. This parameter enables to print the expected context along with the actual one upon mismatch only. The output is separated by double exclamation marks (!!), first the actual context, then the expected one. In the examples below, the `full,mismatch` parameters print the expected full context along with the actual one because the user part of the contexts mismatches. However, when using a solitary `mismatch`, it only checks the type part of the context. The expected context is not printed because the type part of the contexts matches.

```
$ strace --secontext=full,mismatch -e statx stat /home/user/file
statx(AT_FDCWD, "/home/user/file"
[system_u:object_r:user_home_t:s0!!unconfined_u:object_r:user_home_t:s0], ...

$ strace --secontext=mismatch -e statx stat /home/user/file
statx(AT_FDCWD, "/home/user/file" [user_home_t:s0], ...
```

SELinux context mismatches often cause access control issues associated with SELinux. The mismatches printed in the system call traces can significantly expedite the checks of SELinux context correctness. The system call traces can also explain specific kernel behavior with respect to access control checks.

(BZ#2038992)

The `--cyclictest-threshold` option has been added to the rteval utility

With this enhancement, the `--cyclictest-threshold=USEC` option has been added to the rteval test suite. Using this option you can specify a threshold value. The rteval test run ends immediately if any latency measurements exceed this threshold value. When latency expectations are not met, the run aborts with a failure status.

(BZ#2012285)

### 4.10. FILE SYSTEMS AND STORAGE

RHEL 8.6 is compatible with RHEL 9 XFS images

With this update, RHEL 8.6 is now able to use RHEL 9 XFS images. RHEL 9 XFS guest images must have `bigtime` and inode btree counters (`inobtcount`) on-disk capabilities allowed in order to mount the guest image with RHEL 8.6. Note that file systems created with `bigtime` and `inobtcount` features are not compatible with versions earlier than RHEL 8.6.

(BZ#2022903, BZ#2024201)

Options in Samba utilities have been renamed and removed for a consistent user experience

The Samba utilities have been improved to provide a consistent command-line interface. These improvements include renamed and removed options. Therefore, to avoid problems after the update, review your scripts that use Samba utilities, and update them, if necessary.

Samba 4.15 introduces the following changes to the Samba utilities:
Previously, Samba command-line utilities silently ignored unknown options. To prevent unexpected behavior, the utilities now consistently reject unknown options.

Several command-line options now have a corresponding `smb.conf` variable to control their default value. See the man pages of the utilities to identify if a command-line option has an `smb.conf` variable name.

By default, Samba utilities now log to standard error (`stderr`). Use the `--debug-stdout` option to change this behavior.

The `--client-protection=off|sign|encrypt` option has been added to the common parser.

The following options have been renamed in all utilities:

- `--kerberos` to `--use-kerberos=required|desired|off`
- `--krb5-ccache` to `--use-krb5-ccache=CCACHE`
- `--scope` to `--netbios-scope=SCOPE`
- `--use-ccache` to `--use-winbind-ccache`

The following options have been removed from all utilities:

- `--encrypt`
- `--use-winbind-ccache`
- `--netbios-scope`
- `--use-ccache`
- `--use-winbind-ccache`

To avoid duplicate options, certain options have been removed or renamed from the following utilities:

- `ndrdump`: `-l` is no longer available for `--load-dso`
- `net`: `-l` is no longer available for `--long`
- `sharesec`: `-V` is no longer available for `--viewsddl`
- `smbcquotas`: `--user` has been renamed to `--quota-user`
- `nmbd`: `--log-stdout` has been renamed to `--debug-stdout`
- `smbd`: `--log-stdout` has been renamed to `--debug-stdout`
- `winbindd`: `--log-stdout` has been renamed to `--debug-stdout`

(BZ#2062117)

Compiler barrier changed to static inline function `compiler_barrier` to avoid name conflict with function pointers

This enhancement provides additional features and a patch for a potential data corruption bug. The compiler barrier is now set to a static inline function `compiler_barrier`. No name conflict occurs with the hardware store barrier, when implementing hardware fencing for non-temporal memcpy variants, while using a function pointer. As a result, RHEL 8.6 now includes `pmdk` version 1.11.1.
4.11. HIGH AVAILABILITY AND CLUSTERS

The `pcmk_delay_base` parameter may now take different values for different nodes

When configuring a fence device, you now can specify different values for different nodes with the `pcmk_delay_base` parameter. This allows a single fence device to be used in a two-node cluster, with a different delay for each node. This helps prevent a situation where each node attempts to fence the other node at the same time. To specify different values for different nodes, you map the host names to the delay value for that node using a similar syntax to `pcmk_host_map`. For example, `node1:0;node2:10s` would use no delay when fencing node1 and a 10-second delay when fencing node2.

Specifying automatic removal of location constraint following resource move

When you execute the `pcs resource move` command, this adds a constraint to the resource to prevent it from running on the node on which it is currently running. A new `--autodelete` option for the `pcs resource move` command, previously available as a Technology Preview, is now fully supported. When you specify this option, the location constraint that the command creates is automatically removed once the resource has been moved.

Detailed Pacemaker status display for internal errors

If Pacemaker cannot execute a resource or fence agent for some reason, for example the agent is not installed or there has been an internal timeout, the Pacemaker status displays now show a detailed exit reason for the internal error.

Support for special characters inside `pcmk_host_map` values

The `pcmk_host_map` property now supports special characters inside `pcmk_host_map` values using a backslash (\) in front of the value. For example, you can specify `pcmk_host_map="node3:plug\ 1"` to include a space in the host alias.

`pcs` support for OCF Resource Agent API 1.1 standard

The `pcs` command-line interface now supports OCF 1.1 resource and STONITH agents. An OCF 1.1 agent’s metadata must comply with the OCF 1.1 schema. If an OCF 1.1 agent’s metadata does not comply with the OCF 1.1 schema, `pcs` considers the agent invalid and will not create or update a resource of the agent unless the `--force` option is specified. The `pcsd` Web UI and `pcs` commands for listing agents omit OCF 1.1 agents with invalid metadata from the listing.

An OCF agent that declares that it implements any OCF version other than 1.1, or does not declare a version at all, is validated against the OCF 1.0 schema. Validation issues are reported as warnings, but for those agents it is not necessary to specify the `--force` option when creating or updating a resource of the agent.

New fencing agent for OpenShift

(BZ#2009889)

(BZ#1082146)

(BZ#1990784)

(BZ#1470834)

(BZ#1376538)

(BZ#1936833)
The fence_kubevirt fencing agent is now available for use with RHEL High Availability on Red Hat OpenShift Virtualization. For information on the fence_kubevirt agent, see the fence_kubevirt(8) man page.

(BZ#1977588)

4.12. DYNAMIC PROGRAMMING LANGUAGES, WEB AND DATABASE SERVERS

A new module stream: php:8.0

RHEL 8.6 adds PHP 8.0, which provides a number of bug fixes and enhancements over version 7.4

Notable enhancements include:

- New named arguments are order-independent and self-documented, and enable you to specify only required parameters.
- New attributes enable you to use structured metadata with PHP’s native syntax.
- New union types enable you to use native union type declarations that are validated at runtime instead of PHPDoc annotations for a combination of types.
- Internal functions now more consistently raise an Error exception instead of warnings if parameter validation fails.
- The Just-In-Time compilation has improved the performance.
- The Xdebug debugging and productivity extension for PHP has been updated to version 3. This version introduces major changes in functionality and configuration compared to Xdebug 2.

To install the php:8.0 module stream, use:

```bash
# yum module install php:8.0
```

If you want to upgrade from the php:7.4 stream, see Switching to a later stream.

For details regarding PHP usage on RHEL 8, see Using the PHP scripting language.

(BZ#1978356, BZ#2027285)

A new module stream: perl:5.32

RHEL 8.6 introduces Perl 5.32, which provides a number of bug fixes and enhancements over Perl 5.30 distributed in RHEL 8.3.

Notable enhancement include:

- Perl now supports unicode version 13.0.
- The qr qoute-like operator has been enhanced.
- The POSIX::mblen(), mbtowc, and wctomb functions now work on shift state locales and are thread-safe on C99 and above compilers when executed on a platform that has locale thread-safety; the length parameters are now optional.
- The new experimental *isa* infix operator tests whether a given object is an instance of a given class or a class derived from it.

- Alpha assertions are no longer experimental.

- Script assertions are no longer experimental.

- Feature checks are now faster.

- Perl can now dump compiled patterns before optimization.

To upgrade from an earlier perl module stream, see Switching to a later stream.

(BZ#2021471)

**A new package: nginx-mod-devel**

A new nginx-mod-devel package has been added to the nginx:1.20 module stream. The package provides all necessary files, including RPM macros and nginx source code, for building external dynamic modules for nginx.

(BZ#1991787)

**MariaDB Galera now includes an upstream version of the garbd systemd service and a wrapper script**

MariaDB 10.3 and MariaDB 10.5 in RHEL 8 include a Red Hat version of garbd systemd service and a wrapper script for the galera package in the /usr/lib/systemd/system/garbd.service and /usr/sbin/garbd-wrapper files, respectively.

In addition to the Red Hat version of these files, RHEL 8 now also provides an upstream version. The upstream files are located at /usr/share/doc/galera/garb-systemd and /usr/share/doc/galera/garbd.service.

RHEL 9 provides only the upstream version of these files, located at /usr/lib/systemd/system/garbd.service and /usr/sbin/garb-systemd.

(BZ#2042306, BZ#2042298, BZ#2050543, BZ#2050546)

**4.13. COMPILERS AND DEVELOPMENT TOOLS**

**New command for capturing glibc optimization data**

The new ld.so --list-diagnostics command captures data that influences glibc optimization decisions, such as IFUNC selection and glibc-hwcaps configuration, in a single machine-readable file.

(BZ#2023420)

**glibc string functions are now optimized for Fujitsu A64FX**

With this update, glibc string functions exhibit increased throughput and reduced latency on A64FX CPUs.

(BZ#1929928)

**New UTF-8 locale en_US@ampm with 12-hour clock**
With this update, you can now use a new UTF-8 locale `en_US@ampm` with a 12-hour clock. This new locale can be combined with other locales by using the `LC_TIME` environment variable.

(BZ#2000374)

**New location for libffi's self-modifying code**

With this update libffi's self-modifying code takes advantage of a feature in the RHEL 8 kernel to create a suitable file independent of any file system. As a result, libffi's self-modifying code no longer depends on making part of the filesystem insecure.

(BZ#1875340)

**Updated GCC Toolset 11**

GCC Toolset 11 is a compiler toolset that provides recent versions of development tools. It is available as an Application Stream in the form of a Software Collection in the AppStream repository.

Notable changes introduced with RHEL 8.6 include:

- The GCC compiler has been updated to version 11.2.1.
- `annobin` has been updated to version 10.23.

The following tools and versions are provided by GCC Toolset 10:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>GCC</td>
<td>11.2.1</td>
</tr>
<tr>
<td>GDB</td>
<td>10.2</td>
</tr>
<tr>
<td>Valgrind</td>
<td>3.17.0</td>
</tr>
<tr>
<td>SystemTap</td>
<td>4.5</td>
</tr>
<tr>
<td>Dyninst</td>
<td>11.0.0</td>
</tr>
<tr>
<td>binutils</td>
<td>2.36.1</td>
</tr>
<tr>
<td>elfutils</td>
<td>0.185</td>
</tr>
<tr>
<td>dwz</td>
<td>0.14</td>
</tr>
<tr>
<td>make</td>
<td>4.3</td>
</tr>
<tr>
<td>strace</td>
<td>5.13</td>
</tr>
<tr>
<td>ltrace</td>
<td>0.7.91</td>
</tr>
<tr>
<td>annobin</td>
<td>10.23</td>
</tr>
</tbody>
</table>
To install GCC Toolset 11, run the following command as root:

```
# yum install gcc-toolset-11
```

To run a tool from GCC Toolset 11:

```
$ scl enable gcc-toolset-11 tool
```

To run a shell session where tool versions from GCC Toolset 11 override system versions of these tools:

```
$ scl enable gcc-toolset-11 bash
```

For more information about usage, see Using GCC Toolset.

The GCC Toolset 11 components are available in the two container images:

- `rhel8/gcc-toolset-11-toolchain`, which includes the GCC compiler, the GDB debugger, and the
  `make` automation tool.

- `rhel8/gcc-toolset-11-perftools`, which includes the performance monitoring tools, such as
  SystemTap and Valgrind.

To pull a container image, run the following command as root:

```
# podman pull registry.redhat.io/<image_name>
```

Note that only the GCC Toolset 11 container images are now supported. Container images of earlier
GCC Toolset versions are deprecated.

For details regarding the container images, see Using the GCC Toolset container images.

(BZ#1996862)

**GDB disassembler now supports the new arch14 instructions**

With this update, GDB is able to disassemble new arch14 instructions.

(BZ#2012818)

**LLVM Toolset rebased to version 13.0.1**

LLVM Toolset has been upgraded to version 13.0.1. Notable changes include:

- Clang now supports guaranteed tail calls with statement attributes `[[clang::musttail]]` in C++
  and `__attribute__((musttail))` in C.

- Clang now supports the `-Wreserved-identifier` warning, which warns developers when using
  reserved identifiers in their code.

- Clang’s `-Wshadow` flag now also checks for shadowed structured bindings.

- Clang’s `-Wextra` now also implies `Wnull-pointer-subtraction`.

(BZ#2001133)

**Rust Toolset rebased to 1.58.1**
The **Rust Toolset** has been rebased to version 1.58.1. Notable changes include:

- The Rust compiler now supports the 2021 edition of the language, featuring disjoint capture in closure, `Intotlterator` for arrays, a new Cargo feature resolver, and more.
- Added Cargo support for new custom profiles.
- Cargo deduplicates compiler errors.
- Added new open range patterns.
- Added captured identifiers in format strings.

For further information, see:

- Rust 1.55
- Rust 1.56
- Rust 1.57
- Rust 1.58

(BZ#2002883)

**Go rebased to version 1.17.7**

The Go language has been updated to version 1.17.7. The Go rebase includes the following notable features:

- Added an option to convert slices to array pointers.
- Added support for `//go:build` lines.
- Improvements to function call performance on amd64
- Function arguments are formatted more clearly in stack traces
- Functions containing closures can be inlined
- Reduced resource consumption in x509 certificate parsing.

(BZ#2014088)

**pcp rebased to 5.3.5**

The **pcp** package has been rebased to version 5.3.5. Notable changes include:

- Added new `pmieconf(1)` rules for CPU and disk saturation.
- Improved stability and scalability of `pmproxy(1)` service.
- Improved service latency and robustness of `pmlogger(1)` service.
- Added new performance metrics related to electrical power.
- Added new features in the `pcp-htop(1)` utility.
- Added new features in the `pcp-atop(1)` utility.
- Updated Nvidia GPU metrics.
- Added new Linux kernel KVM and networking metrics.
- Added a new MongoDB metrics agent.
- Added a new sockets metrics agent and `pcp-ss(1)` utility.
- Disabled `pmcd(1)` and `pmproxy(1)` Avahi service advertising by default.

(BZ#1991763)

The **grafana** package rebased to version 7.5.11

The **grafana** package has been rebased to version 7.5.11. Notable changes include:

- Added a new **prepare time series** transformation for backward compatibility of panels that do not support the new data frame format.

(BZ#1993214)

**grafana-pcp** rebased to 3.2.0

The **grafana-pcp** package has been rebased to version 3.2.0. Notable changes include:

- Added a new MS SQL server dashboard for PCP Redis.
- Added visibility of empty histogram buckets in the PCP Vector eBPF/BCC Overview dashboard.
- Fixed a bug where the **metric()** function of PCP Redis did not return all metric names.

(BZ#1993149)

**js-d3-flame-graph** rebased to 4.0.7

The **js-d3-flame-graph** package has been rebased to version 4.0.7. Notable changes include:

- Added new blue and green color scheme.
- Added functionality to display flame graph context.

(BZ#1993194)

**A new module: log4j:2**

A new **log4j:2** module is now available in the AppStream repository. This module contains **Apache Log4j 2**, which is a Java logging utility and a library enabling you to output log statements to a variety of output targets.

**Log4j 2** provides significant improvements over **Log4j 1**. Notably, **Log4j 2** introduces enhancements to the **Logback** framework and fixes some inherent problems in the **Logback** architecture.

To install the **log4j:2** module stream, use:

```
# yum module install log4j:2
```

(BZ#1937468)
4.14. IDENTITY MANAGEMENT

**ansible-freeipa** is now available in the AppStream repository with all dependencies

Previously in RHEL 8, before installing the **ansible-freeipa** package, you first had to enable the Ansible repository and install the **ansible** package. In RHEL 8.6 and RHEL 9, you can install **ansible-freeipa** without any preliminary steps. Installing **ansible-freeipa** automatically installs the **ansible-core** package, a more basic version of **ansible**, as a dependency. Both **ansible-freeipa** and **ansible-core** are available in the `rhel-9-for-x86_64-appstream-rpms` repository.

**ansible-freeipa** in RHEL 8.6 and RHEL 9 contains all the modules that it contained in RHEL 8.

(JIRA:RHELPLAN-100359)

IdM now supports the automountlocation, automountmap, and automountkey Ansible modules

With this update, the **ansible-freeipa** package contains the **ipaautomountlocation**, **ipaautomountmap**, and **ipaautomountkey** modules. You can use these modules to configure directories to be mounted automatically for IdM users logged in to IdM clients in an IdM location. Note that currently, only direct maps are supported.

(JIRA:RHELPLAN-79161)

An alternative to the traditional RHEL ansible-freeipa repository: Ansible Automation Hub

With this update, you can download **ansible-freeipa** modules from the Ansible Automation Hub (AAH) instead of downloading them from the standard RHEL repository. By using AAH, you can benefit from the faster updates of the **ansible-freeipa** modules available in this repository.

In AAH, **ansible-freeipa** roles and modules are distributed in the collection format. Note that you need an Ansible Automation Platform (AAP) subscription to access the content on the AAH portal. You also need **ansible** version 2.9 or later.

The redhat.rhel_idm collection has the same content as the traditional **ansible-freeipa** package. However, the collection format uses a fully qualified collection name (FQCN) that consists of a namespace and the collection name. For example, the `redhat.rhel_idm.ipadnsconfig` module corresponds to the `ipadnsconfig` module in **ansible-freeipa** provided by a RHEL repository. The combination of a namespace and a collection name ensures that the objects are unique and can be shared without any conflicts.

(JIRA:RHELPLAN-103147)

**ansible-freeipa** modules can now be executed remotely on IdM clients

Previously, **ansible-freeipa** modules could only be executed on IdM servers. This required your Ansible administrator to have SSH access to your IdM server, causing a potential security threat. With this update, you can execute **ansible-freeipa** modules remotely on systems that are IdM clients. As a result, you can manage IdM configuration and entities in a more secure way.

To execute **ansible-freeipa** modules on an IdM client, choose one of the following options:

- Set the `hosts` variable of the playbook to an IdM client host.
- Add the `ipa_context: client` line to the playbook task that uses the **ansible-freeipa** module.

You can set the `ipa_context` variable to `client` on an IdM server, too. However, the server context usually provides better performance. If `ipa_context` is not set, **ansible-freeipa** checks if it is running on a server or a client, and sets the context accordingly. Note that executing an **ansible-freeipa** module...
with context set to server on an IdM client host raises an error of missing libraries.

(JIRA:RHELPLAN-103146)

Identity Management now supports SHA384withRSA signing by default

With this update, the Certificate Authority (CA) in IdM supports the SHA-384 With RSA Encryption signing algorithm. SHA384withRSA is compliant with the Federal Information Processing Standard (FIPS).

(BZ#1731484)

SSSD default SSH hashing value is now consistent with the OpenSSH setting

The default value of ssh_hash_known_hosts has been changed to false. It is now consistent with the OpenSSH setting, which does not hash host names by default.

However, if you need to continue to hash host names, add ssh_hash_known_hosts = True to the [ssh] section of the /etc/sssd/sssd.conf configuration file.

(BZ#2015070)

samba rebased to version 4.15.5

The samba packages have been upgraded to upstream version 4.15.5, which provides bug fixes and enhancements over the previous version:

- Options in Samba utilities have been renamed and removed for a consistent user experience
- Server multi-channel support is now enabled by default.
- The SMB2_22, SMB2_24, and SMB3_10 dialects, which were only used by Windows technical previews, have been removed.

Back up the database files before starting Samba. When the smbd, nmbd, or winbind services start, Samba automatically updates its tdb database files. Note that Red Hat does not support downgrading tdb database files.

After updating Samba, verify the /etc/samba/smb.conf file using the testparm utility.

For further information about notable changes, read the upstream release notes before updating.

(BZ#2013596)

Directory Server rebased to version 1.4.3.28

The 389-ds-base packages have been upgraded to upstream version 1.4.3, which provides a number of bug fixes and enhancements over the previous version:

- A potential deadlock in replicas has been fixed.
- The server no longer terminates unexpectedly when the dnaInterval is set to 0.
- The performance of connection handling has been improved.
- Improved performance of targetfilter in access control instructions (ACI).

(BZ#2016014)
Directory Server now stores memory-mapped files of databases on a tmpfs file system

In Directory Server, the nsslapd-db-home-directory parameter defines the location of memory-mapped files of databases. This enhancement changes the default value of the parameter from /var/lib/dirsrv/slapd-instance_name/db/ to /dev/shm/. As a result, with the internal databases stored on a tmpfs file system, the performance of Directory Server increases.

(BZ#1780842)

4.15. THE WEB CONSOLE

Smart card authentication for sudo and SSH from the web console

Previously, it was not possible to use smart card authentication to obtain sudo privileges or use SSH in the web console. With this update, Identity Management users can use a smart card to gain sudo privileges or to connect to a different host with SSH.

NOTE

It is only possible to use one smart card to authenticate and gain sudo privileges. Using a separate smart card for sudo is not supported.

(JIRA:RHELPLAN-95126)

Cockpit now supports using an existing TLS certificate

With this enhancement, the certificate does not have strict file permission requirements any more (such as root:cockpit-ws 0640), and thus it can be shared with other services.

(JIRA:RHELPLAN-103855)

4.16. RED HAT ENTERPRISE LINUX SYSTEM ROLES

The Firewall RHEL System Role has been added in RHEL 8

The rhel-system-roles.firewall RHEL System Role was added to the rhel-system-roles package. As a result, administrators can automate their firewall settings for managed nodes.

(BZ#1854988)

Full Support for HA Cluster RHEL System Role

The High Availability Cluster (HA Cluster) role, previously available as a Technology Preview, is now fully supported. The following notable configurations are available:

- Configuring fence devices, resources, resource groups, and resource clones including meta attributes and resource operations
- Configuring resource location constraints, resource colocation constraints, resource order constraints, and resource ticket constraints
- Configuring cluster properties
- Configuring cluster nodes, custom cluster names and node names
- Configuring multi-link clusters
• Configuring whether clusters start automatically on boot

Running the role removes any configuration not supported by the role or not specified when running the role.

The HA Cluster System Role does not currently support SBD.

(BZ#1893743)

The Networking System Role now supports OWE

Opportunistic Wireless Encryption (OWE) is a mode of opportunistic security for Wi-Fi networks that provides encryption of the wireless medium but no authentication, such as public hot spots. OWE uses encryption between Wi-Fi clients and access points, protecting them from sniffing attacks. With this enhancement, the Networking RHEL System role supports OWE. As a result, administrators can now use the Networking System Role to configure connections to Wi-Fi networks which use OWE.

(BZ#1993379)

The Networking System Role now supports SAE

In Wi-Fi protected access version 3 (WPA3) networks, the simultaneous authentication of equals (SAE) method ensures that the encryption key is not transmitted. With this enhancement, the Networking RHEL System role supports SAE. As a result, administrators can now use the Networking System Role to configure connections to Wi-Fi networks, which use WPA-SAE.

(BZ#1993311)

The Cockpit RHEL System Role is now supported

With this enhancement, you can install and configure the web console in your system. Consequently, you can manage web console in an automated manner.

(BZ#2021661)

Add support for raid_level for LVM volumes

The Storage RHEL System Role can now specify the raid_level parameter for LVM volumes. As a result, LVM volumes can be grouped into RAIDs using the lvmraid feature.

(BZ#2016514)

The NBDE client System Role supports systems with static IP addresses

Previously, restarting a system with a static IP address and configured with the NBDE client System Role would change the system’s IP address. With this change, systems with static IP addresses are supported by the NBDE client System Role, and their IP addresses do not change after a reboot.

(BZ#1985022)

Support for cached volumes is available in the Storage System Role

Storage RHEL System Role can now create and manage cached LVM logical volumes. LVM cache can be used to improve performance of slower logical volumes by temporarily storing subsets of an LV’s data on a smaller, faster device, for example an SSD.

(BZ#2016511)

Support to add Elasticsearch username and password for authentication from rsyslog
This update adds the Elasticsearch username and password parameters to the logging System Role, to enable the rsyslog to authenticate to Elasticsearch using username and password.

(BZ#2010327)

Ansible Core support for the RHEL System Roles

As of RHEL 8.6 GA release, Ansible Core is provided, with a limited scope of support, to enable RHEL supported automation use cases. Ansible Core replaces Ansible Engine which was previously provided in a separate repository. Ansible Core is available in the AppStream repository for RHEL. For more details on the supported use cases, see Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories. Users must manually migrate their systems from Ansible Engine to Ansible Core.

For details on that, see Using Ansible in RHEL 8.6 and later.

(BZ#2012316)

The network RHEL System Role now supports both named and numeric routing tables in static routes.

This update adds support for both the named and numeric routing tables in static routes, which is a prerequisite for supporting the policy routing (for example, source routing). The users can define policy routing rules later to instruct the system which table to use to determine the correct route. As a result, after the user specifies the table attribute in the route, the system can add routes into the routing table.

(BZ#2031521)

The Certificate role consistently uses "Ansible_managed" comment in its hook scripts

With this enhancement, the Certificate role generates pre-scripts and post-scripts to support providers, to which the role inserts the "Ansible managed" comment using the Ansible standard "ansible_managed" variable:

- /etc/certmonger/pre-scripts/script_name.sh
- /etc/certmonger/post-scripts/script_name.sh

The comment indicates that the script files should not be directly edited because the Certificate role can overwrite the file. As a result, the configuration files contain a declaration stating that the configuration files are managed by Ansible.

(BZ#2054364)

The Terminal session recording System Role uses the "Ansible_managed" comment in its managed configuration files

The Terminal session recording role generates 2 configuration files:

- /etc/sssd/conf.d/sssd-session-recording.conf
- /etc/tlog/tlog-rec-session.conf

With this update, the Terminal session recording role inserts the Ansible managed comment into the configuration files, using the standard Ansible variable ansible_managed. The comment indicates that the configuration files should not be directly edited because the Terminal session recording role can
overwrite the file. As a result, the configuration files contain a declaration stating that the configuration files are managed by Ansible.

(BZ#2054363)

Microsoft SQL System Role now supports customized repository for disconnected or Satellite subscriptions

Previously, users in disconnected environments that needed to pull packages from a custom server or Satellite users that needed to point to Satellite or Capsule had no support from Microsoft SQL Role. This update fixes it, by enabling users to provide a customized URL to use for RPM key, client and server mssql repositories. If no URL is provided, the mssql role uses the official Microsoft servers to download RPMs.

(BZ#2038256)

The Microsoft SQL System Role consistently uses "Ansible_managed" comment in its managed configuration files

The mssql role generates the following configuration file:

- /var/opt/mssql/mssql.conf

With this update, the Microsoft SQL role inserts the "Ansible managed" comment to the configuration files, using the Ansible standard ansible_managed variable. The comment indicates that the configuration files should not be directly edited because the mssql role can overwrite the file. As a result, the configuration files contain a declaration stating that the configuration files are managed by Ansible.

(BZ#2057651)

Support to all bonding options added to the Networking System Role

This update provides support to all bonding options to the Networking RHEL System Role. Consequently, it enables you to flexibly control the network transmission over the bonded interface. As a result, you can control the network transmission over the bonded interface by specifying several options to that interface.

(BZ#2008931)

NetworkManager supports specifying a network card using its PCI address

Previously, during setting a connection profile, NetworkManager was only allowed to specify a network card using either its name or MAC address. In this case, the device name is not stable and the MAC address requires inventory to maintain record of used MAC addresses. Now, you can specify a network card based on its PCI address in a connection profile.

(BZ#1695634)

A new option auto_gateway controls the default route behavior

Previously, the DEFROUTE parameter was not configurable with configuration files but only manually configurable by naming every route. This update adds a new auto_gateway option in the ip configuration section for connections, with which you can control the default route behavior. You can configure auto_gateway in the following ways:

- If set to true, default gateway settings apply to a default route.
- If set to false, the default route is removed.
• If unspecified, the network role uses the default behavior of the selected network_provider.

(BZ#1897565)

The VPN role consistently uses Ansible_managed comment in its managed configuration files

The VPN role generates the following configuration file:

- /etc/ipsec.d/mesh.conf
- /etc/ipsec.d/policies/clear
- /etc/ipsec.d/policies/private
- /etc/ipsec.d/policies/private-or-clear

With this update, the VPN role inserts the Ansible managed comment to the configuration files, using the Ansible standard ansible_managed variable. The comment indicates that the configuration files should not be directly edited because the VPN role can overwrite the file. As a result, the configuration files contain a declaration stating that the configuration files are managed by Ansible.

(BZ#2054365)

New source parameter in the Firewall System Role

You can now use the source parameter of the Firewall System Role to add or remove sources in the firewall configuration.

(BZ#1932678)

The Networking System Role now uses the ‘Ansible managed’ comment in its managed configuration files

When using the initscripts provider, the Networking System Role now generates commented ifcfg files in the /etc/sysconfig/network-scripts directory. The Networking role inserts the Ansible managed comment using the Ansible standard ansible_managed variable. The comment declares that an ifcfg file is managed by Ansible, and indicates that the ifcfg file should not be edited directly as the Networking role will overwrite the file. The Ansible managed comment is added when the provider is initscripts. When using the Networking role with the nm (NetworkManager) provider, the ifcfg file is managed by NetworkManager and not by the Networking role.

(BZ#2057656)

New feature: Set firewall default zone Changing the Default Zone

Zones represent a concept to manage incoming traffic more transparently. The zones are connected to networking interfaces or assigned a range of source addresses. Firewall rules for each zone are managed independently enabling the administrator to define complex firewall settings and apply them to the traffic. This feature allows setting the default zone used as the default zone to assign interfaces to, same as firewall-cmd --set-default-zone zone-name.

(BZ#2022458)

The Metrics System Role now generates files with the proper ansible_managed comment in the header
Previously, the Metrics role did not add an `ansible_managed` header comment to files generated by the role. With this fix, the Metrics role adds the `ansible_managed` header comment to files it generates, and as a result, users can easily identify files generated by the Metrics role.

(BZ#2057645)

The Postfix System Role now generates files with the proper `ansible_managed` comment in the header

Previously, the Postfix role did not add an `ansible_managed` header comment to files generated by the role. With this fix, the Postfix role adds the `ansible_managed` header comment to files it generates, and as a result, users can easily identify files generated by the Postfix role.

(BZ#2057661)

### 4.17. VIRTUALIZATION

**Mediated devices are now supported by virtualization CLIs on IBM Z**

Using `virt-install` or `virt-xml`, you can now attach mediated devices to your virtual machines (VMs), such as vfio-ap and vfio-ccw. This for example enables more flexible management of DASD storage devices and cryptographic coprocessors on IBM Z hosts. In addition, using `virt-install`, you can create a VM that uses an existing DASD mediated device as its primary disk. For instructions to do so, see the Configuring and Managing Virtualization in RHEL 8 guide.

(BZ#1995125)

**Windows 11 and Windows Server 2022 guests are supported**

RHEL 8 now supports using Windows 11 and Windows Server 2022 as the guest operating systems on KVM virtual machines.

(BZ#2036863)

### 4.18. RHEL IN CLOUD ENVIRONMENTS

**RHEL 8 virtual machines are now supported on certain ARM64 hosts on Azure**

Virtual machines that use RHEL 9 as the guest operating system are now supported on Microsoft Azure hypervisors running on Ampere Altra ARM-based processors.

(BZ#1949614)

**cloud-init supports user data on Microsoft Azure**

The `--user-data` option has been introduced for the `cloud-init` utility. Using this option, you can pass scripts and metadata from the Azure Instance Metadata Service (IMDS) when setting up a RHEL 8 virtual machine on Azure.

(BZ#2023940)

**cloud-init supports the VMWare GuestInfo datasource**

With this update, the `cloud-init` utility is able to read the datasource for VMWare guestinfo data. As a result, using `cloud-init` to set up RHEL 8 virtual machines on VMWare vSphere is now more efficient and reliable.

(BZ#2026587)
4.19. SUPPORTABILITY

A new package: rig

RHEL 8 introduces the rig package, which provides the rig system monitoring and event handling utility.

The rig utility is designed to assist system administrators and support engineers in diagnostic data collection for issues that are seemingly random in their occurrence, or occur at inopportune times for human intervention.

(BZ#1888705)

sos report now offers an estimate mode run

This sos report update adds the --estimate-only option with which you can approximate the disk space required for collecting an sos report from a RHEL server. Running the sos report --estimate-only command:

- executes a dry run of sos report
- mimics all plugins consecutively and estimates their disk size.

Note that the final disk space estimation is very approximate. Therefore, it is recommended to double the estimated value.

(BZ#1873185)

Red Hat Support Tool now uses Hydra APIs

The Red Hat Support Tool has moved from the deprecated Strata APIs to the new Hydra APIs. This has no impact on functionality. However, if you have configured the firewall to allow only the Strata API /rs/ path explicitly, update it to /support/ to ensure the firewall works correctly.

In addition, due to this change, you can now download files greater than 5 GB when using the Red Hat Support Tool.

(BZ#2018194)

Red Hat Support Tool now supports Red Hat Secure FTP

When using Red Hat Support Tool, you can now upload files to the case by the Red Hat Secure FTP. Red Hat Secure FTP is a more secure replacement of the deprecated Dropbox utility that Red Hat Support Tool used to support in its earlier versions.

(BZ#2018195)

Red Hat Support Tool now supports S3 APIs

The Red Hat Support Tool now uses S3 APIs to upload files to the Red Hat Technical Support case. As a result, users can upload a file greater than 1 GB to the case directly.

(BZ#1767195)

4.20. CONTAINERS

container-tools:4.0 stable stream is now available
The **container-tools:4.0** stable module stream, which contains the Podman, Buildah, Skopeo, and runc tools is now available. This update provides bug fixes and enhancements over the previous version.

For instructions on how to upgrade from an earlier stream, see [Switching to a later stream](#).

(JIRA:RHELPLAN-100175)

**The NFS storage is now available**

You can now use the NFS file system as a backend storage for containers and images if your file system has xattr support.

(JIRA:RHELPLAN-75169)

**The container-tools:rhel8 module has been updated**

The **container-tools:rhel8** module, which contains the Podman, Buildah, Skopeo, crun, and runc tools is now available. This update provides a list of bug fixes and enhancements over the previous version.

Notable changes include:

- Due to the changes in the network stack, containers created by Podman v3 and earlier will not be usable in v4.0
- The native overlay file system is usable as a rootless user
- Support for NFS storage within a container
- Downgrading to earlier versions of Podman is not supported unless all containers are destroyed and recreated

Podman tool has been upgraded to version 4.0, for further information about notable changes, see the [upstream release notes](#).

(JIRA:RHELPLAN-100174)

**Universal Base Images are now available on Docker Hub**

Previously, Universal Base Images were only available from the Red Hat container catalog. With this enhancement, Universal Base Images are also available from Docker Hub as a [Verified Publisher image](#).

(JIRA:RHELPLAN-101137)

**A podman container image is now available**

The [registry.redhat.io/rhel8/podman](#) container image, previously available as a Technology Preview, is now fully supported. The [registry.redhat.io/rhel8/podman](#) container image is a containerized implementation of the podman package. The podman tool manages containers and images, volumes mounted into those containers, and pods made of groups of containers.

(JIRA:RHELPLAN-57941)

**Podman now supports auto-building and auto-running pods using a YAML file**

The podman play kube command automatically builds and runs multiple pods with multiple containers in the pods using a YAML file.

(JIRA:RHELPLAN-108830)
Podman now has ability to source subUID and subGID ranges from IdM

The subUID and subGID ranges can now be managed by IdM. Instead of deploying the same /etc/subuid and /etc/subgid files onto every host, you can now define range in a single central storage. You have to modify the /etc/nsswitch.conf file and add sss to the services map line: services: files sss.

For more details, see Chapter 32. Managing subID ranges manually in IdM documentation.

(JIRA:RHELPLAN-101133)

The openssl container image is now available

The openssl image provides an openssl command-line tool for using the various functions of the OpenSSL crypto library. Using the OpenSSL library, you can generate private keys, create certificate signing requests (CSRs), and display certificate information.

The openssl container image is available in these repositories:

- registry.redhat.io/rhel8/openssl
- registry.access.redhat.com/ubi8/openssl

(JIRA:RHELPLAN-101138)
CHAPTER 5. BUG FIXES

This part describes bugs fixed in Red Hat Enterprise Linux 8.6 that have a significant impact on users.

5.1. INSTALLER AND IMAGE CREATION

The network --defroute option now works correctly in the %include script

Previously, the network --defroute option got ignored when used in the %include script during the kickstart installation. As a consequence, the device was set as the default route.

With this update, the kickstart installation does not ignore the network --defroute option added in the %include script and the network connection is configured as expected.

(BZ#1990145)

Users can now specify user accounts in the RHEL for Edge Installer blueprint

Previously, performing an update on your blueprint without a user account defined in the RHEL for Edge Commit for the upgrade, such as adding a rpm package, would cause users to be locked out of their system, after the upgrade was applied. It caused users to have redefine user accounts when upgrading an existing system. This issue has been fixed to allow users to specify user accounts in the RHEL for Edge Installer blueprint, that creates a user on the system at installation time, rather than having the user as part of the ostree commit.

(BZ#1951936)

5.2. SOFTWARE MANAGEMENT

Running createrepo_c --update on a modular repository now preserves modular metadata in it

Previously, when running the createrepo_c --update command on an already existing modular repository without the original source of modular metadata present, the default policy was to remove all additional metadata including modular metadata from this repository, which, consequently, broke it. To preserve metadata, it required running the createrepo_c --update command with the additional --keep-all-metadata option.

With this update, you can preserve modular metadata on a modular repository by running createrepo_c --update without any additional option.

To remove additional metadata, you can use the new --discard-additional-metadata option.

(BZ#1992209)

5.3. SHELLS AND COMMAND-LINE TOOLS

Errors during the installation of the info subpackage do not happen anymore

Previously the fix-info-dir script expected the existence of a /dev/null file. With a new version of the texinfo package for software documentation, the installation of the info subpackage does not fail on systems that do not contain the /dev/null special file. Now the fix-info-dir script does not expect the existence of the /dev/null file, and avoids the possibility of an infinite loop.

(BZ#2022201)
ReaR backs up a system with an unused LVM physical volume correctly

Previously, ReaR produced an incorrect disk layout when an unused LVM physical volume (PV) was present on the system. As a result, ReaR commands that need to produce the disk layout, such as the mkrescue, mkbackup, mkbackuponly, savelayout commands, aborted with the error message:

```
ERROR: LVM 'lvmdev' entry in /var/lib/rear/layout/disklayout.conf where volume_group or device is empty or more than one word
```

With this update, ReaR now comments out unused PVs in the disk layout file and is thus able to back up a system with unused PVs correctly.

(BZ#2048454)

ReaR does not incorrectly exclude multipath devices from the backup

Previously, ReaR was incorrectly excluding certain multipath devices whose names contained the names of multipath devices that should have been excluded from the backup.

For example, if a device named /dev/mapper/mpatha was excluded from the backup, then a second device named /dev/mapper/mpathaa would be incorrectly excluded as well. This would occur with more than 26 multipath devices.

The bug has been fixed and ReaR now does not exclude multipath devices from the backup unless they should be excluded. Note that you have to specify AUTOEXCLUDE_MULTIPATH=n in the ReaR configuration file if there are multipath devices that should be included in the backup, otherwise ReaR excludes all multipath devices automatically. This behavior has not changed.

(BZ#2049091)

5.4. SECURITY

Remote users are no longer repetitively prompted to access smart cards

Previously, the polkit policy for the pcsd daemon incorrectly requested user interaction. As a consequence, non-local and non-privileged users could not access smart cards and encountered large numbers of prompts. With this update, the pcsclite package policy no longer includes the interactive prompts. As a result, remote card users are no longer repeatedly asked for privilege escalation.

For additional information about adjusting the policy to escalate privileges of non-privileged users, see Controlling access to smart cards using polkit in Security hardening in RHEL product documentation.

(BZ#1928154)

64-bit IBM Z systems no longer become unbootable when installing in FIPS mode

Previously, the fips-mode-setup command with the --no-bootcfg option did not execute the zipl tool. Because fips-mode-setup regenerates the initial RAM disk (initrd), and the resulting system needs an update of zipl internal state to boot, this put 64-bit IBM Z systems into an unbootable state after installing in FIPS mode. With this update, fips-mode-setup now executes zipl on 64-bit IBM Z systems even if invoked with --no-bootcfg, and as a result, the newly installed system boots successfully.

(BZ#2020295)

crypto-policies can disable ChaCha20 in OpenSSL

Previously, the crypto-policies component used a wrong keyword to disable the ChaCha20 cipher in
OpenSSL. As a consequence, use of ChaCha20 in TLS 1.2 in OpenSSL could not be disabled through crypto-policies. With this update, crypto-policies use the -CHACHA20 keyword instead of the -CHACHA20-POLY1305 keyword. As a result, you can now use crypto-policies to disable the use of the ChaCha20 cipher in OpenSSL for both TLS 1.2 and TLS 1.3.

(BZ#2023734)

systemd can now execute files from /home/user/bin

Previously, systemd services could not execute files from the /home/user/bin/ directory because the SELinux policy did not include the policy rules that allow such access. Consequently, the systemd services failed and eventually logged the Access Vector Cache (AVC) denial Audit messages. This update adds the missing SELinux rules that allow access, and systemd services can now correctly execute commands from /home/user/bin/.

(BZ#1860443)

STIG-specific default banner text removed from other profiles

Previously, banner text from the STIG profile was used as default by other profiles that did not have a default text defined, such as CIS. As a consequence, systems using these profiles were configured with the specific text required by DISA. With this update, a generic default text was created and a standard CIS banner aligned with the guidelines was defined. As a result, profiles based on guidelines which explicitly require a text banner are now aligned with the requirements and set the correct text.

(BZ#1983061)

ANSSI Enhanced Profile correctly selects the "Ensure SELinux State is Enforcing" rule

Previously, the ANSSI Enhanced profile (anssi_bp28_enhanced) did not select the "Ensure SELinux State is Enforcing" (selinux_state) rule. This update modified the rule selection and now the ANSSI Enhanced Profile selects the "Ensure SELinux State is Enforcing" rule.

(BZ#2053587)

Descriptions for restorecon and seunshare SSG rules fixed

Previously, descriptions for rules "Record Any Attempts to Run restorecon" (CCE-80699-2) and "Record Any Attempts to Run seunshare" (CCE-80933-5) were incorrect. With this update, the descriptions of these rules are aligned with the automated OVAL check. As a result, applying the fix recommended in the description now correctly fixes these rules.

(BZ#2023569)

The CIS profile no longer automatically disables IPv6

Previously, the CIS profile for RHEL 8 provided inappropriate automated remediation for recommendation "3.6 Disable IPv6", which disabled IPv6 by configuring /etc/modprobe.d/ipv6.conf to prevent the IPv6 module from loading. This could have undesired effects on the dependent features and services. In RHEL 8 CIS Benchmark v1.0.1, the recommendation 3.6 must be implemented manually, and therefore the RHEL8 CIS profiles do not apply any remediation for this configuration item. As a result, the CIS profile is aligned with the benchmark and does not disable IPv6 automatically. To disable IPv6 manually by configuring GRUB2 or sysctl settings as recommended by CIS, see How do I disable or enable the IPv6 protocol in Red Hat Enterprise Linux?.

(BZ#1990736)

CIS profile no longer blocks the SSH service
Previously, the `xccdf_org.ssgproject.content_rule_file_permissions_sshd_private_key` rule by default set the permissions to `640` on SSH private keys. As a consequence, the SSH daemon did not start. This update removes the `file_permissions_sshd_private_key` rule from the CIS profile and as a result, the SSH service works correctly.

(BZ#2002850)

**Files in /usr/share/audit/sample-rules are now accepted by SCAP rules**

Previously, according to the description of SCAP rules `xccdf_org.ssgproject.content_rule_audit_ospp_general` and `xccdf_org.ssgproject.content_rule_audit_immutable_login_uids`, users were able to make systems compliant by copying appropriate files from the `/usr/share/audit/sample-rules` directory. However, OVAL checks of these rules failed, and the system was consequently marked as non-compliant after the scan. With this update, the OVAL checks now accept the files from `/usr/share/audit/sample-rules`, and the SCAP rules pass successfully.

(BZ#2000264)

**ANSSI Kickstart now reserves enough disk space**

Previously, GUI installation required more disk space than ANSSI Kickstart reserved in the `/usr` partition. As a consequence, RHEL 8.6 GUI installations failed, with an error message stating that **At least 429 MB more space needed on the /usr filesystem**. This update increases the disk space for the `/usr` partition, and RHEL 8.6 installations using the ANSSI Kickstarts provided in the `scap-security-guide` now completes successfully.

(BZ#2058033)

**Remediations of GRUB2 arguments are now persistent**

Previously, the remediations for GRUB2 rules that set kernel arguments were using incorrect procedures and the configuration changes were not persistent across kernel upgrades. As a consequence, the remediations had to be reapplied with every kernel upgrade. With this update, remediations use the `grubby` tool that configures GRUB2 in a persistent way.

(BZ#2030966)

**usbguard-notifier no longer logs too many error messages to the Journal**

Previously, the `usbguard-notifier` service did not have inter-process communication (IPC) permissions for connecting to the `usbguard-daemon` IPC interface. Consequently, `usbguard-notifier` failed to connect to the interface, and it wrote a corresponding error message to the Journal. Because `usbguard-notifier` started with the `--wait` option, which ensured that `usbguard-notifier` attempted to connect to the IPC interface each second after a connection failure, by default, the log contained an excessive amount of these messages soon.

With this update, `usbguard-notifier` does not start with `--wait` by default. The service attempts to connect to the daemon only three times in the 1-second intervals. As a result, the log contains three such error messages at maximum.

(BZ#2000000)

**Ambient capabilities are now applied correctly to non-root users**

As a safety measure, changing a UID (User Identifier) from root to non-root nullifies permitted, effective, and ambient sets of capabilities.

However, the `pam_cap.so` module is unable to set ambient capabilities because a capability needs to be
in both the permitted and the inheritable set to be in the ambient set. In addition, the permitted set gets nullified after changing the UID (for example by using the `setuid` utility), so the ambient capability cannot be set.

To fix this problem, the `pam_cap.so` module now supports the `keepcaps` option, which allows a process to retain its permitted capabilities after changing the UID from root to non-root. The `pam_cap.so` module now also supports the `defer` option, which causes `pam_cap.so` to reapply ambient capabilities within a callback to `pam_end()`. This callback can be used by other applications after changing the UID.

Therefore, if the `su` and `login` utilities are updated and PAM-compliant, you can now use `pam_cap.so` with the `keepcaps` and `defer` options to set ambient capabilities for non-root users.

(BZ#1950187)

**The `usbguard-selinux` package is no longer dependent on `usbguard`**

Previously, the `usbguard-selinux` package was dependent on the `usbguard` package. This, in combination with other dependencies of these packages, led to file conflicts when installing `usbguard`. As a consequence, this prevented the installation of `usbguard` on certain systems. With this version, `usbguard-selinux` no longer depends on `usbguard`, and as a result, `yum` can install `usbguard` correctly.

(BZ#1963271)

**`audisp-remote` now correctly detects the availability of the remote locations**

Previously, the `audisp-remote` plugin did not detect that remote services became unavailable. As a consequence, the `audisp-remote` process would enter a state with high CPU usage. With this update, `audisp-remote` can properly detect remote services becoming unavailable. As a result, the process no longer enters a high-CPU-usage state.

(BZ#1906065)

**Clevis no longer stops on certain configurations before automated unlocking**

Previously, the Clevis utility, which performs automated unlocking of LUKS-encrypted volumes, stopped on certain system configurations. Consequently, encrypted volumes were not unlocked automatically, and the administrator had to provide a passphrase manually. In some cases, Clevis restarted after the administrator pressed Enter and unlocked the encrypted volumes. With this update, the utility has been fixed to not stop on these configurations, and the process of automated unlocking now works properly.

(BZ#2018292)

### 5.5. KERNEL

**The `dmidecode --type 17` command now successfully decodes DDR5 memory information**

Previously, the `dmidecode` command failed to decode the DDR5 memory information. Consequently, `dmidecode --type 17` returned the `<OUT OF SPEC>` message. The latest update of the package (`dmidecode-3.3-3.el8`) has fixed this problem. As a result, `dmidecode --type 17` now successfully decodes DDR5 memory information.

(BZ#2027665)

**kdump no longer fails on KVM virtual machines that use the default amount of memory**

Previously, `kdump` failed on some kernel-based virtual machines (KVM) that uses the default amount of memory. Consequently, the crash kernel failed to capture the crash dump file with following error:
/bin/sh: error while loading shared libraries: libtinfo.so.6: cannot open shared object file: No such file or directory

With this update, the problem has been fixed and `kdump` works correctly on KVM virtual machines that use the default amount of memory.

(BZ#2004000)

**Tunnel offloading now works as expected and supports the available hardware**

Previously, the driver was not setting certain feature flags. Hence, tunnel offloading was not working as expected. In this update, the driver sets the required flags to enable tunnel offloading and works as expected.

(BZ#1910885)

**Fixed the kernel warning while setting the rx ring buffer to max**

Previously, an internal function expecting clean input was called with a reused and already initialized structure. It caused the kernel to give the warning message: “missing unregister, handled but fix driver”. This update fixes the bug, reinitializing the structure before trying to register it again.

(BZ#2040171)

### 5.6. FILE SYSTEMS AND STORAGE

**The multipathd.socket unit file no longer disables multipathd after too many startup attempts**

Previously, the starting conditions for `multipathd` in the `multipath.service` unit file differed from the triggering conditions in `multipathd.socket`. Consequently, the unit file repeatedly tried to start `multipathd` and failed. This resulted in disabling `multipathd` after too many failed attempts. With this fix, the starting conditions for `multipathd.socket` and `multipathd.service` have been set to the same values. As a result, the `multipathd.socket` unit file no longer attempts to start `multipathd where the starting conditions for `multipathd.service are not met.

(BZ#2008101)

**Protection uevents no longer cause reload failure of multipath devices**

Previously, when a `read-only` path device was rescanned, the kernel sent out two write protection uevents - one with the device set to `read/write`, and the following with the device set to `read-only`. Consequently, upon detection of the `read/write` uevent on a path device, `multipathd` tried to reload the multipath device, which caused a reload error message. With this update, `multipathd` now checks that all the paths are set to `read/write` before reloading a device read/write. As a result, `multipathd` no longer tries to reload `read/write` whenever a `read-only` device is rescanned.

(BZ#2009624)

### 5.7. COMPILERS AND DEVELOPMENT TOOLS

**The -j flag now works when used in a Makefile**

Previously, when you added the `-j` flag to `MAKEFLAGS` inside the Makefile, the targets were built sequentially instead of in parallel. This bug has been fixed, and now the targets are built at the same time when you use the `-j` flag in the Makefile.
**Statically linked applications no longer crash**

Previously, the initialization code of the dynamic loader, which is linked into statically linked binaries, did not initialize a link map variable correctly. Consequently, statically linked applications crashed if `LD_LIBRARY_PATH` contained a dynamic token string. With this update statically linked applications no longer crash.

**pthread_once() in glibc has been fixed to correctly support C++ exceptions**

Previously, the `pthread_once()` implementation could result in a hang when using `libstdc++` library functions. For example `libstdc++`'s `std::call_once()` called a function that threw an exception which would result in a hang. With this update, `pthread_once()` is fixed and no longer hangs when an exception is thrown.

**5.8. IDENTITY MANAGEMENT**

Certmonger can now automatically renew SCEP certificates with AD when `challengePassword` is required for enrollment

Previously, requests for renewal of SCEP certificates sent by certmonger to an Active Directory (AD) Network Device Enrollment Service (NDES) server included the `challengePassword` used to originally obtain the certificate. However, AD treats `challengePassword` as a one-time password (OTP). As a consequence, the renewal request was rejected.

This update adds the `challenge_password_otp` option to certmonger. When enabled, this option prevents certmonger from sending the OTP with the SCEP renewal request. The administrator must also add the `DisableRenewalSubjectNameMatch` entry with a value of 1 to the `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Cryptography\MSCEP` subkey in the AD registry. With this modification, AD no longer requires the signer certificate and requested certificate subject names to match. As a result, the SCEP certificate renewal is successful.

To configure certmonger and the AD server for SCEP renewals to work:

1. Open `regedit` on the AD server.
2. In the `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Cryptography\MSCEP` subkey, add a new 32-bit REG_DWORD entry `DisableRenewalSubjectNameMatch` and set its value to 1.
3. On the server where certmonger is running, open the `/etc/certmonger/certmonger.conf` file and add the following section:

   ```
   [scep]
   challenge_password_otp = yes
   ```
4. Restart certmonger:

   ```
   # systemctl restart certmonger
   ```
FreeRADIUS proxy server no longer stops working when a second FreeRADIUS server is unavailable

When a FreeRADIUS server is configured as a proxy server it forwards request messages to another FreeRADIUS server. Previously, if the connection between these two servers was interrupted, the FreeRADIUS proxy server stopped working. With this fix, the FreeRADIUS proxy server is now able to reestablish a connection when the other server becomes available.

(BZ#2030173)

Authenticating to Directory Server in FIPS mode with PBKDF2-hashed passwords now works as expected

When Directory Server runs in Federal Information Processing Standard (FIPS) mode, the PK11_ExtractKeyValue() function is not available. As a consequence, users with a password-based key derivation function 2 (PBKDF2) hashed password could not authenticate to the server when FIPS mode was enabled. With this update, Directory Server now uses the PK11_Decrypt() function to get the password hash data. As a result, authenticating to Directory Server in FIPS mode now works for users with PBKDF2-hashed passwords.

(BZ#2033398)

5.9. RED HAT ENTERPRISE LINUX SYSTEM ROLES

A playbook using the Metrics role completes successfully on multiple runs even if the Grafana admin password is changed

Previously, changes to the Grafana admin user password after running the Metrics role with the metrics_graph_service: yes boolean caused failure on subsequent runs of the Metrics role. This led to failures of playbooks using the Metrics role, and the affected systems were only partially set up for performance analysis. Now, the Metrics role uses the Grafana deployment API when it is available and no longer requires knowledge of username or password to perform the necessary configuration actions. As a result, a playbook using the Metrics role completes successfully on multiple runs even if the administrator changes the Grafana admin password.

(BZ#1967321)

The SSHD System Role uses the correct template file

In RHEL 8.5, the SSHD System Role used a wrong template file. As a consequence, the generated sshd_config file did not contain the # Ansible managed comment. The missing comment did not affect any functionality on the system. With this update, the system role uses the correct template file and sshd_config contains the correct # Ansible managed comment.

(BZ#2040038)

The Networking System Role no longer fails to set a DNS search domain if IPv6 is disabled

Previously, the nm_connection_verify() function of the libnm library did not ignore the DNS search domain if the IPv6 protocol was disabled. As a consequence, when you used the Networking RHEL System Role and set dns_search together with ipv6_disabled: true, the System Role failed with the following error:

```
nm-connection-error-quark: ipv6.dns-search: this property is not allowed for 'method=ignore' (7)
```

With this update, the nm_connection_verify() function ignores the DNS search domain if IPv6 is disabled. As a consequence, you can use dns_search as expected, even if IPv6 is disabled.
The nm provider in the Networking System Role now correctly manages bridges

Previously, if you used the initscripts provider, the Networking System Role created an ifcfg file which configured NetworkManager to mark bridge interfaces as unmanaged. Also, NetworkManager failed to detect followup initscript actions. For example, the down and absent actions of initscript provider will not change the NetworkManager’s understanding on unmanaged state of this interface if not reloading the connection after the down and absent actions. With this fix, the Networking System Role uses the NM.Client.reload_connections_async() function to reload NetworkManager on managed hosts with NetworkManager 1.18. As a result, NetworkManager manages the bridge interface when switching the provider from initscript to nm.

The SSH server role now detects FIPS mode and handles tasks correctly in FIPS mode

Previously, when managing RHEL8 and older systems in FIPS mode, one of the default hostkeys was not allowed to be created. As a consequence, the SSH server role operation failed to generate the not allowed key type when invoked. With this fix, the SSH server role detects FIPS mode and adjusts default hostkey list accordingly. As a result, the SSH server role can now manage systems in FIPS mode with default hostkeys configuration.

The Logging System Role no longer calls tasks multiple times

Previously, the Logging role was calling tasks multiple times that should have been called only once. As a consequence, the extra task calls slowed down the execution of the role. With this fix, the Logging role was changed to call the tasks only once, improving the Logging role performance.

RHEL System Roles now handle multi-line ansible_managed comments in generated files

Previously, some of the RHEL System Roles were using # {{ ansible_managed }} to generate some of the files. As a consequence, if a customer had a custom multi-line ansible_managed setting, the files would be generated incorrectly. With this fix, all of the system roles use the equivalent of {{ ansible_managed | comment }} when generating files so that the ansible_managed string is always properly commented, including multi-line ansible_managed values. Consequently, generated files have the correct multi-line ansible_managed value.

The Logging role no longer misses quotes for the immark module interval value

Previously, the "interval" field value for the immark module was not properly quoted, because the immark module was not properly configured. This fix ensures that the "interval" value is properly quoted. Now, the immark module works as expected.

The group option no longer keeps certificates inaccessible to the group

Previously, when setting the group for a certificate, the mode was not set to allow group read permission. As a consequence, group members were unable to read certificates issued by the Certificate role. With this fix, the group setting now ensures that the file mode includes group read permission. As a result, the certificates issued by the Certificate role for groups are accessible by the group members.

Red Hat Enterprise Linux 8.6 8.6 Release Notes

56
Chapter 5. Bug Fixes

(BZ#2021683)

The `/etc/tuned/kernel_settings/tuned.conf` file has a proper `ansible_managed` header

Previously, the Kernel settings RHEL System Role had a hard-coded value for the `ansible_managed` header in the `/etc/tuned/kernel_settings/tuned.conf` file. Consequently, users could not provide their custom `ansible_managed` header. In this update, the problem has been fixed so that the `kernel_settings` updates the header of `/etc/tuned/kernel_settings/tuned.conf` with user’s `ansible_managed` setting. As a result, `/etc/tuned/kernel_settings/tuned.conf` has a proper `ansible_managed` header.

(BZ#2047504)

The `logging_purge_confs` option no longer fails to delete unnecessary configuration files

Previously, the `logging_purge_confs` variable was prepared to delete unnecessary logging configuration files, but failed to clean them up. Consequently, even though the `logging_purge_confs` variable was set to true, unnecessary configuration files were not cleaned up, but left in the configuration directory. This issue is now fixed and the `logging_purge_confs` variable has been redefined to work as follows.

- If `logging_purge_confs` is set to `true`, it removes files in `rsyslog.d` which do not belong to any `rpm` packages. That includes configuration files generated by the previous `logging` role run. The `logging_purge_confs` default value is `false`.

(BZ#2040812)

Fixed a typo to support `active-backup` for the correct bonding mode

Previously, there was a typo, `active_backup`, in supporting the InfiniBand port while specifying `active-backup` bonding mode. Due to this typo, the connection failed to support the correct bonding mode for the InfiniBand bonding port. This update fixes the typo by changing bonding mode to `active-backup`. The connection now successfully supports the InfiniBand bonding port.

(BZ#2064388)

Configuration by the Metrics role now follows symbolic links correctly

When the `mssql pcp` package is installed, the `mssql.conf` file is located in `/etc/pcp/mssql/` and is targeted by the symbolic link `/var/lib/pcp/pmdas/mssql/mssql.conf`. Previously, however, the Metrics role overwrote the symbolic link instead of following it and configuring `mssql.conf`. Consequently, running the Metrics role changed the symbolic link to a regular file and the configuration therefore only affected the `/var/lib/pcp/pmdas/mssql/mssql.conf` file. This resulted in a failed symbolic link, and the main configuration file `/etc/pcp/mssql/mssql.conf` was not affected by the configuration. The issue is now fixed and the `follow: yes` option to follow the symbolic link has been added to the Metrics role. As a result, the Metrics role preserves the symbolic links and correctly configures the main configuration file.

(BZ#2058655)

The Kernel settings System Role now correctly installs `python3-configobj`

Previously, the Kernel settings role returned an error that the `python3-configobj` package could not be found. The role failed to find the package because it did not install `python3-configobj` on managed hosts. With this update, the role now installs `python3-configobj` on managed hosts and works correctly.

(BZ#2058772)

The Kdump System Role does not ignore hosts anymore

Previously, the Kdump role ignored managed nodes that do not have memory reserved for crash kernel,
and consequently completed with the “Success” status even when not configuring the system correctly. The role has been redesigned to fail in cases where managed nodes do not have memory reserved for crash kernel, and to prompt the user to set the `kdump_reboot_ok` variable to `true` to correctly configure kdump on managed nodes. As a result, the Kdump role now does not ignore hosts, and either completes successfully with the correct configuration, or fails with an error message describing what users need to do to fix the issue.

(BZ#2029605)

**The Firewall System Role now reloads the firewall immediately when target changes**

Previously, the Firewall System Role was not reloading the firewall when the `target` parameter has been changed. With this fix, the Firewall role reloads the firewall when the `target` changes, and as a result, the `target` change is immediate and available for subsequent operations.

(BZ#2057172)

**Default pcsd permissions for HA Cluster System Role now allow access for group haclient**

Previously, when a user ran the HA Cluster System Role with the default `pcsd` permissions that were set with the `ha_cluster_pcs_permission_list` variable, only members of the group `hacluster` had access to the cluster. With this fix, the default `pcsd` permissions allow the group `haclient` to manage the cluster and all members of `haclient` can now access and manage the cluster.

(BZ#2049747)

5.10. VIRTUALIZATION

**Hot unplugging an IBMVFC device on PowerVM now works as expected**

Previously, when using a virtual machine (VM) with a RHEL 8 guest operating system on the PowerVM hypervisor, attempting to remove an IBM Power Virtual Fibre Channel (IBMVFC) device from the running VM failed. Instead, it displayed an `outstanding translation` error. The underlying code has been fixed and live hot unplugs of IBMVFC device now work correctly on PowerVM.

(BZ#1959020)

5.11. CONTAINERS

**Rootless containers created in RHEL 8.5 and earlier using fuse-overlayfs now recognize removed files**

Previously, in RHEL 8.4 and earlier, rootless images and containers were created or stored using the fuse-overlayfs file system. Using such images and containers in RHEL 8.5 and later introduced problems for unprivileged users using the overlayfs implementation provided by the kernel and who had removed files or directories from a container or from an image in RHEL 8.4. This problem did not apply to containers created by the root account.

As a consequence, files or directories that were removed from a container or from an image were marked as such using the whiteout format when using the fuse-overlayfs file system. However, due to differences in the format, the kernel overlayfs implementation did not recognize the whiteout format created by fuse-overlayfs. As a result, any removed files or directories still appeared. This problem did not apply to containers created by the root account.

With this update, the problem is solved.

(JIRA:RHELPLAN-92741)
CHAPTER 6. TECHNOLOGY PREVIEWS

This part provides a list of all Technology Previews available in Red Hat Enterprise Linux 8.6.

For information on Red Hat scope of support for Technology Preview features, see Technology Preview Features Support Scope.

6.1. SHELLS AND COMMAND-LINE TOOLS

ReaR available on the 64-bit IBM Z architecture as a Technology Preview

Basic Relax and Recover (ReaR) functionality is now available on the 64-bit IBM Z architecture as a Technology Preview. You can create a ReaR rescue image on IBM Z only in the z/VM environment. Backing up and recovering logical partitions (LPARs) has not been tested.

The only output method currently available is Initial Program Load (IPL). IPL produces a kernel and an initial ramdisk (initrd) that can be used with the ziPL bootloader.

**WARNING**

Currently, the rescue process reformats all the DASDs (Direct Attached Storage Devices) connected to the system. Do not attempt a system recovery if there is any valuable data present on the system storage devices. This also includes the device prepared with the ziPL bootloader, ReaR kernel, and initrd that were used to boot into the rescue environment. Ensure to keep a copy.

For more information, see Using a ReaR rescue image on the 64-bit IBM Z architecture.

(BZ#1868421)

6.2. NETWORKING

AF_XDP available as a Technology Preview

**Address Family eXpress Data Path (AF_XDP)** socket is designed for high-performance packet processing. It accompanies XDP and grants efficient redirection of programmatically selected packets to user space applications for further processing.

(BZ#1633143)

XDP features that are available as Technology Preview

Red Hat provides the usage of the following eXpress Data Path (XDP) features as unsupported Technology Preview:

- Loading XDP programs on architectures other than AMD and Intel 64-bit. Note that the libxdp library is not available for architectures other than AMD and Intel 64-bit.

- The XDP hardware offloading.

(BZ#1889737)
Multi-protocol Label Switching for TC available as a Technology Preview

The Multi-protocol Label Switching (MPLS) is an in-kernel data-forwarding mechanism to route traffic flow across enterprise networks. In an MPLS network, the router that receives packets decides the further route of the packets based on the labels attached to the packet. With the usage of labels, the MPLS network has the ability to handle packets with particular characteristics. For example, you can add tc filters for managing packets received from specific ports or carrying specific types of traffic, in a consistent way.

After packets enter the enterprise network, MPLS routers perform multiple operations on the packets, such as push to add a label, swap to update a label, and pop to remove a label. MPLS allows defining actions locally based on one or multiple labels in RHEL. You can configure routers and set traffic control (tc) filters to take appropriate actions on the packets based on the MPLS label stack entry (lse) elements, such as label, traffic class, bottom of stack, and time to live.

For example, the following command adds a filter to the enp0s1 network interface to match incoming packets having the first label 12323 and the second label 45832. On matching packets, the following actions are taken:

- the first MPLS TTL is decremented (packet is dropped if TTL reaches 0)
- the first MPLS label is changed to 549386
- the resulting packet is transmitted over enp0s2, with destination MAC address 00:00:5E:00:53:01 and source MAC address 00:00:5E:00:53:02

```
# tc filter add dev enp0s1 ingress protocol mpls_uc flower mpls lse depth 1 label 12323 lse depth 2 label 45832 \
action mpls dec_ttl pipe \
action mpls modify label 549386 pipe \
action pedit ex munge eth dst set 00:00:5E:00:53:01 pipe \
action pedit ex munge eth src set 00:00:5E:00:53:02 pipe \
action mirred egress redirect dev enp0s2
```

(BZ#1814836, BZ#1856415)

The systemd-resolved service is now available as a Technology Preview

The systemd-resolved service provides name resolution to local applications. The service implements a caching and validating DNS stub resolver, an Link-Local Multicast Name Resolution (LLMNR), and Multicast DNS resolver and responder.

Note that, even if the systemd package provides systemd-resolved, this service is an unsupported Technology Preview.

(BZ#1906489)

The nispor package is now available as a Technology Preview

The nispor package is now available as a Technology Preview, which is a unified interface for Linux network state querying. It provides a unified way to query all running network status through the python and C api, and rust crate. nispor works as the dependency in the nmstate tool.

You can install the nispor package as a dependency of nmstate or as an individual package.

- To install nispor as an individual package, enter:
# yum install nispor

- To install nispor as a dependency of nmstate, enter:

  # yum install nmstate

nispor is listed as the dependency.

For more information on using nispor, refer to /usr/share/doc/nispor/README.md file.

(BZ#1848817)

## 6.3. KERNEL

The kexec fast reboot feature is available as a Technology Preview

The kexec fast reboot feature continues to be available as a Technology Preview. The kexec fast reboot significantly speeds the boot process as the kernel enables booting directly into the second kernel without passing through the Basic Input/Output System (BIOS) first. To use this feature:

1. Load the kexec kernel manually.
2. Reboot the operating system.

(BZ#1769727)

The accel-config package available as a Technology Preview

The accel-config package is now available on Intel EM64T and AMD64 architectures as a Technology Preview. This package helps in controlling and configuring data-streaming accelerator (DSA) subsystem in the Linux Kernel. Also, it configures devices through sysfs (pseudo-filesystem), saves and loads the configuration in the json format.

(BZ#1843266)

SGX available as a Technology Preview

Software Guard Extensions (SGX) is an Intel® technology for protecting software code and data from disclosure and modification. The RHEL kernel partially supports SGX v1 and v1.5. The version 1 enables platforms using the Flexible Launch Control mechanism to use the SGX technology.

(BZ#1660337)

eBPF available as a Technology Preview

Extended Berkeley Packet Filter (eBPF) is an in-kernel virtual machine that allows code execution in the kernel space, in the restricted sandbox environment with access to a limited set of functions.

The virtual machine includes a new system call bpf(), which enables creating various types of maps, and also allows to load programs in a special assembly-like code. The code is then loaded to the kernel and translated to the native machine code with just-in-time compilation. Note that the bpf() syscall can be successfully used only by a user with the CAP_SYS_ADMIN capability, such as the root user. See the bpf(2) manual page for more information.

The loaded programs can be attached onto a variety of points (sockets, tracepoints, packet reception) to receive and process data.
There are numerous components shipped by Red Hat that utilize the eBPF virtual machine. Each component is in a different development phase. All components are available as a Technology Preview, unless a specific component is indicated as supported.

The following notable eBPF components are currently available as a Technology Preview:

- **AF_XDP**, a socket for connecting the eXpress Data Path (XDP) path to user space for applications that prioritize packet processing performance.

(BZ#1559616)

**The Intel data streaming accelerator driver for kernel is available as a Technology Preview**

The Intel data streaming accelerator driver (IDXD) for the kernel is currently available as a Technology Preview. It is an Intel CPU integrated accelerator and includes a shared work queue with process address space ID (pasid) submission and shared virtual memory (SVM).

(BZ#1837187)

**Soft-RoCE available as a Technology Preview**

Remote Direct Memory Access (RDMA) over Converged Ethernet (RoCE) is a network protocol that implements RDMA over Ethernet. Soft-RoCE is the software implementation of RoCE which maintains two protocol versions, RoCE v1 and RoCE v2. The Soft-RoCE driver, `rdma_rxe`, is available as an unsupported Technology Preview in RHEL 8.

(BZ#1605216)

**The stmmac driver is available as a Technology Preview**

Red Hat provides the usage of `stmmac` for Intel® Elkhart Lake systems on a chip (SoCs) as an unsupported Technology Preview.

(BZ#1905243)

### 6.4. FILE SYSTEMS AND STORAGE

**File system DAX is now available for ext4 and XFS as a Technology Preview**

In Red Hat Enterprise Linux 8, the file system DAX is available as a Technology Preview. DAX provides a means for an application to directly map persistent memory into its address space. To use DAX, a system must have some form of persistent memory available, usually in the form of one or more Non-Volatile Dual In-line Memory Modules (NVDIMMs), and a file system that provides the capability of DAX must be created on the NVDIMM(s). Also, the file system must be mounted with the `dax` mount option. Then, a `mmap` of a file on the dax-mounted file system results in a direct mapping of storage into the application’s address space.

(BZ#1627455)

**OverlayFS**

OverlayFS is a type of union file system. It enables you to overlay one file system on top of another. Changes are recorded in the upper file system, while the lower file system remains unmodified. This allows multiple users to share a file-system image, such as a container or a DVD-ROM, where the base image is on read-only media.

OverlayFS remains a Technology Preview under most circumstances. As such, the kernel logs warnings when this technology is activated.
Full support is available for OverlayFS when used with supported container engines (podman, cri-o, or buildah) under the following restrictions:

- OverlayFS is supported for use only as a container engine graph driver. Its use is supported only for container COW content, not for persistent storage. You must place any persistent storage on non-OverlayFS volumes. You can use only the default container engine configuration: one level of overlay, one lowerdir, and both lower and upper levels are on the same file system.

- Only XFS is currently supported for use as a lower layer file system.

Additionally, the following rules and limitations apply to using OverlayFS:

- The OverlayFS kernel ABI and user-space behavior are not considered stable, and might change in future updates.

- OverlayFS provides a restricted set of the POSIX standards. Test your application thoroughly before deploying it with OverlayFS. The following cases are not POSIX-compliant:
  - Lower files opened with O_RDONLY do not receive st_atime updates when the files are read.
  - Lower files opened with O_RDONLY, then mapped with MAP_SHARED are inconsistent with subsequent modification.
  - Fully compliant st_ino or d_ino values are not enabled by default on RHEL 8, but you can enable full POSIX compliance for them with a module option or mount option. To get consistent inode numbering, use the xino=on mount option.

You can also use the redirect_dir=on and index=on options to improve POSIX compliance. These two options make the format of the upper layer incompatible with an overlay without these options. That is, you might get unexpected results or errors if you create an overlay with redirect_dir=on or index=on, unmount the overlay, then mount the overlay without these options.

- To determine whether an existing XFS file system is eligible for use as an overlay, use the following command and see if the ftype=1 option is enabled:
  
  ```
  # xfs_info /mount-point | grep ftype
  ```

- SELinux security labels are enabled by default in all supported container engines with OverlayFS.

- Several known issues are associated with OverlayFS in this release. For details, see Non-standard behavior in the Linux kernel documentation: https://www.kernel.org/doc/Documentation/filesystems/overlayfs.txt.

For more information about OverlayFS, see the Linux kernel documentation: https://www.kernel.org/doc/Documentation/filesystems/overlayfs.txt.

(BZ#1690207)

**Stratis is now available as a Technology Preview**

Stratis is a new local storage manager. It provides managed file systems on top of pools of storage with additional features to the user.

Stratis enables you to more easily perform storage tasks such as:
Manage snapshots and thin provisioning

- Automatically grow file system sizes as needed
- Maintain file systems

To administer Stratis storage, use the **stratis** utility, which communicates with the **stratisd** background service.

Stratis is provided as a Technology Preview.

For more information, see the Stratis documentation: [Setting up Stratis file systems](#).

RHEL 8.3 updated Stratis to version 2.1.0. For more information, see [Stratis 2.1.0 Release Notes](#).

(JIRA:RHELPLAN-1212)

**Setting up a Samba server on an IdM domain member is provided as a Technology Preview**

With this update, you can now set up a Samba server on an Identity Management (IdM) domain member. The new **ipa-client-samba** utility provided by the same-named package adds a Samba-specific Kerberos service principal to IdM and prepares the IdM client. For example, the utility creates the `/etc/samba/smb.conf` with the ID mapping configuration for the **sss** ID mapping back end. As a result, administrators can now set up Samba on an IdM domain member.

Due to IdM Trust Controllers not supporting the Global Catalog Service, AD-enrolled Windows hosts cannot find IdM users and groups in Windows. Additionally, IdM Trust Controllers do not support resolving IdM groups using the Distributed Computing Environment / Remote Procedure Calls (DCE/RPC) protocols. As a consequence, AD users can only access the Samba shares and printers from IdM clients.

For details, see [Setting up Samba on an IdM domain member](#).

(JIRA:RHELPLAN-13195)

**NVMe/TCP is available as a Technology Preview**

Accessing and sharing Nonvolatile Memory Express (NVMe) storage over TCP/IP networks (NVMe/TCP) and its corresponding **nvme-tcp.ko** and **nvmet-tcp.ko** kernel modules have been added as a Technology Preview.

The use of NVMe/TCP as either a storage client or a target is manageable with tools provided by the **nvme-cli** and **nvmetcli** packages.

The NVMe/TCP target Technology Preview is included only for testing purposes and is not currently planned for full support.

(BZ#1696451)

**NVMe/TCP host is available as a Technology Preview**

Nonvolatile Memory Express (NVMe) storage over TCP/IP networks (NVMe/TCP) host with the **nvme-tcp.ko** kernel module is available as a Technology Preview in RHEL 8.6. The NVMe/TCP host is not maintained and is not currently planned for full support.

(BZ#2061577)

### 6.5. HIGH AVAILABILITY AND CLUSTERS
Pacemaker podman bundles available as a Technology Preview

Pacemaker container bundles now run on Podman, with the container bundle feature being available as a Technology Preview. There is one exception to this feature being Technology Preview: Red Hat fully supports the use of Pacemaker bundles for Red Hat Openstack.

(BZ#1619620)

Heuristics in corosync-qdevice available as a Technology Preview

Heuristics are a set of commands executed locally on startup, cluster membership change, successful connect to corosync-qnetd, and, optionally, on a periodic basis. When all commands finish successfully on time (their return error code is zero), heuristics have passed; otherwise, they have failed. The heuristics result is sent to corosync-qnetd where it is used in calculations to determine which partition should be quorate.

(BZ#1784200)

New fence-agents-heuristics-ping fence agent

As a Technology Preview, Pacemaker now provides the fence_heuristics_ping agent. This agent aims to open a class of experimental fence agents that do no actual fencing by themselves but instead exploit the behavior of fencing levels in a new way.

If the heuristics agent is configured on the same fencing level as the fence agent that does the actual fencing but is configured before that agent in sequence, fencing issues an off action on the heuristics agent before it attempts to do so on the agent that does the fencing. If the heuristics agent gives a negative result for the off action it is already clear that the fencing level is not going to succeed, causing Pacemaker fencing to skip the step of issuing the off action on the agent that does the fencing. A heuristics agent can exploit this behavior to prevent the agent that does the actual fencing from fencing a node under certain conditions.

A user might want to use this agent, especially in a two-node cluster, when it would not make sense for a node to fence the peer if it can know beforehand that it would not be able to take over the services properly. For example, it might not make sense for a node to take over services if it has problems reaching the networking uplink, making the services unreachable to clients, a situation which a ping to a router might detect in that case.

(BZ#1775847)

Automatic removal of location constraint following resource move available as a Technology Preview

When you execute the pcs resource move command, this adds a constraint to the resource to prevent it from running on the node on which it is currently running. A new --autodelete option for the pcs resource move command is now available as a Technology Preview. When you specify this option, the location constraint that the command creates is automatically removed once the resource has been moved.

(BZ#1847102)

6.6. IDENTITY MANAGEMENT

Identity Management JSON-RPC API available as Technology Preview

An API is available for Identity Management (IdM). To view the API, IdM also provides an API browser as a Technology Preview.
Previously, the IdM API was enhanced to enable multiple versions of API commands. These enhancements could change the behavior of a command in an incompatible way. Users are now able to continue using existing tools and scripts even if the IdM API changes. This enables:

- Administrators to use previous or later versions of IdM on the server than on the managing client.
- Developers can use a specific version of an IdM call, even if the IdM version changes on the server.

In all cases, the communication with the server is possible, regardless if one side uses, for example, a newer version that introduces new options for a feature.

For details on using the API, see Using the Identity Management API to Communicate with the IdM Server (TECHNOLOGY PREVIEW).

(BZ#1664719)

DNSSEC available as Technology Preview in IdM

Identity Management (IdM) servers with integrated DNS now support DNS Security Extensions (DNSSEC), a set of extensions to DNS that enhance security of the DNS protocol. DNS zones hosted on IdM servers can be automatically signed using DNSSEC. The cryptographic keys are automatically generated and rotated.

Users who decide to secure their DNS zones with DNSSEC are advised to read and follow these documents:

- DNSSEC Operational Practices, Version 2
- Secure Domain Name System (DNS) Deployment Guide
- DNSSEC Key Rollover Timing Considerations

Note that IdM servers with integrated DNS use DNSSEC to validate DNS answers obtained from other DNS servers. This might affect the availability of DNS zones that are not configured in accordance with recommended naming practices.

(BZ#1664718)

ACME available as a Technology Preview

The Automated Certificate Management Environment (ACME) service is now available in Identity Management (IdM) as a Technology Preview. ACME is a protocol for automated identifier validation and certificate issuance. Its goal is to improve security by reducing certificate lifetimes and avoiding manual processes from certificate lifecycle management.

In RHEL, the ACME service uses the Red Hat Certificate System (RHCS) PKI ACME responder. The RHCS ACME subsystem is automatically deployed on every certificate authority (CA) server in the IdM deployment, but it does not service requests until the administrator enables it. RHCS uses the `acmeIPAServerCert` profile when issuing ACME certificates. The validity period of issued certificates is 90 days. Enabling or disabling the ACME service affects the entire IdM deployment.
IMPORTANT

It is recommended to enable ACME only in an IdM deployment where all servers are running RHEL 8.4 or later. Earlier RHEL versions do not include the ACME service, which can cause problems in mixed-version deployments. For example, a CA server without ACME can cause client connections to fail, because it uses a different DNS Subject Alternative Name (SAN).

WARNING

Currently, RHCS does not remove expired certificates. Because ACME certificates expire after 90 days, the expired certificates can accumulate and this can affect performance.

- To enable ACME across the whole IdM deployment, use the `ipa-acme-manage enable` command:

  ```
  # ipa-acme-manage enable
  The ipa-acme-manage command was successful
  ```

- To disable ACME across the whole IdM deployment, use the `ipa-acme-manage disable` command:

  ```
  # ipa-acme-manage disable
  The ipa-acme-manage command was successful
  ```

- To check whether the ACME service is installed and if it is enabled or disabled, use the `ipa-acme-manage status` command:

  ```
  # ipa-acme-manage status
  ACME is enabled
  The ipa-acme-manage command was successful
  ```

(JIRA:RHELPLAN-58596)

6.7. DESKTOP

GNOME for the 64-bit ARM architecture available as a Technology Preview

The GNOME desktop environment is now available for the 64-bit ARM architecture as a Technology Preview. This enables administrators to configure and manage servers from a graphical user interface (GUI) remotely, using the VNC session.

As a consequence, new administration applications are available on the 64-bit ARM architecture. For example: Disk Usage Analyzer (`baobab`), Firewall Configuration (`firewall-config`), Red Hat Subscription Manager (`subscription-manager`), or the Firefox web browser. Using Firefox, administrators can connect to the local Cockpit daemon remotely.

(JIRA:RHELPLAN-27394, BZ#1667225, BZ#1667516, BZ#1724302)
**GNOME desktop on IBM Z is available as a Technology Preview**

The GNOME desktop, including the Firefox web browser, is now available as a Technology Preview on the IBM Z architecture. You can now connect to a remote graphical session running GNOME using VNC to configure and manage your IBM Z servers.

(JIRA:RHELPLAN-27737)

**6.8. GRAPHICS INFRASTRUCTURES**

**VNC remote console available as a Technology Preview for the 64-bit ARM architecture**

On the 64-bit ARM architecture, the Virtual Network Computing (VNC) remote console is available as a Technology Preview. Note that the rest of the graphics stack is currently unverified for the 64-bit ARM architecture.

(BZ#1698565)

**6.9. VIRTUALIZATION**

**AMD SEV and SEV-ES for KVM virtual machines**

As a Technology Preview, RHEL 8 provides the Secure Encrypted Virtualization (SEV) feature for AMD EPYC host machines that use the KVM hypervisor. If enabled on a virtual machine (VM), SEV encrypts the VM's memory to protect the VM from access by the host. This increases the security of the VM.

In addition, the enhanced Encrypted State version of SEV (SEV-ES) is also provided as Technology Preview. SEV-ES encrypts all CPU register contents when a VM stops running. This prevents the host from modifying the VM's CPU registers or reading any information from them.

Note that SEV and SEV-ES work only on the 2nd generation of AMD EPYC CPUs (codenamed Rome) or later. Also note that RHEL 8 includes SEV and SEV-ES encryption, but not the SEV and SEV-ES security attestation.

(BZ#1501618, BZ#1501607, JIRA:RHELPLAN-7677)

**Intel vGPU**

As a Technology Preview, it is now possible to divide a physical Intel GPU device into multiple virtual devices referred to as **mediated devices**. These mediated devices can then be assigned to multiple virtual machines (VMs) as virtual GPUs. As a result, these VMs share the performance of a single physical Intel GPU.

Note that only selected Intel GPUs are compatible with the vGPU feature.

In addition, it is possible to enable a VNC console operated by Intel vGPU. By enabling it, users can connect to a VNC console of the VM and see the VM's desktop hosted by Intel vGPU. However, this currently only works for RHEL guest operating systems.

(BZ#1528684)

**Creating nested virtual machines**

Nested KVM virtualization is provided as a Technology Preview for KVM virtual machines (VMs) running on Intel, AMD64, IBM POWER, and IBM Z systems hosts with RHEL 8. With this feature, a RHEL 7 or RHEL 8 VM that runs on a physical RHEL 8 host can act as a hypervisor, and host its own VMs.
Technology Preview: Select Intel network adapters now provide SR-IOV in RHEL guests on Hyper-V

As a Technology Preview, Red Hat Enterprise Linux guest operating systems running on a Hyper-V hypervisor can now use the single-root I/O virtualization (SR-IOV) feature for Intel network adapters that are supported by the ixgbevf and iavf drivers. This feature is enabled when the following conditions are met:

- SR-IOV support is enabled for the network interface controller (NIC)
- SR-IOV support is enabled for the virtual NIC
- SR-IOV support is enabled for the virtual switch
- The virtual function (VF) from the NIC is attached to the virtual machine

The feature is currently provided with Microsoft Windows Server 2016 and later.

(ESXi hypervisor and SEV-ES is now fully supported)

You can now enable the AMD Secure Encrypted Virtualization-Encrypted State (SEV-ES) to secure RHEL virtual machines (VMs) on VMware’s ESXi hypervisor, versions 7.0.2 and later. This feature was previously introduced in RHEL 8.4 as a Technology Preview. It is now fully supported.

(Sharing files between hosts and VMs using virtiofs)

As a Technology Preview, RHEL 8 now provides the virtio file system (virtiofs). Using virtiofs, you can efficiently share files between your host system and its virtual machines (VM).

(KVM virtualization is usable in RHEL 8 Hyper-V virtual machines)

As a Technology Preview, nested KVM virtualization can now be used on the Microsoft Hyper-V hypervisor. As a result, you can create virtual machines on a RHEL 8 guest system running on a Hyper-V host.

Note that currently, this feature only works on Intel and AMD systems. In addition, nested virtualization is in some cases not enabled by default on Hyper-V. To enable it, see the following Microsoft documentation:

https://docs.microsoft.com/en-us/virtualization/hyper-v-on-windows/user-guide/nested-virtualization

(The Netavark network stack is available as a Technology Preview)

The Netavark is a network stack for containers that is now available as a Technology Preview.

This network stack has the following capabilities:
- Creating, managing, and removing network interfaces, including bridge and MACVLAN interfaces
- Configuring firewall settings, such as network address translation (NAT) and port mapping rules
- IPv4 and IPv6
- Improved capability for containers in multiple networks

The default network stack is CNI. For instructions on how to switch between CNI and Netavark network stacks, see Switching network stack from CNI to Netavark and Switching network stack from Netavark to CNI.

(JIRA:RHELPLAN-100039)

**Toolbox is available as a Technology Preview**

Previously, the Toolbox utility was based on RHEL CoreOS github.com/coreos/toolbox. With this release, Toolbox has been replaced with github.com/containers/toolbox.

(JIRA:RHELPLAN-77238)
CHAPTER 7. DEPRECATED FUNCTIONALITY

This part provides an overview of functionality that has been deprecated in Red Hat Enterprise Linux 8.

Deprecated functionality will likely not be supported in future major releases of this product and is not recommended for new deployments. For the most recent list of deprecated functionality within a particular major release, refer to the latest version of release documentation.

The support status of deprecated functionality remains unchanged within Red Hat Enterprise Linux 8. For information about the length of support, see Red Hat Enterprise Linux Life Cycle and Red Hat Enterprise Linux Application Streams Life Cycle.

 Deprecated hardware components are not recommended for new deployments on the current or future major releases. Hardware driver updates are limited to security and critical fixes only. Red Hat recommends replacing this hardware as soon as reasonably feasible.

A package can be deprecated and not recommended for further use. Under certain circumstances, a package can be removed from a product. Product documentation then identifies more recent packages that offer functionality similar, identical, or more advanced to the one deprecated, and provides further recommendations.

For information regarding functionality that is present in RHEL 7 but has been removed in RHEL 8, see Considerations in adopting RHEL 8.

7.1. INSTALLER AND IMAGE CREATION

Several Kickstart commands and options have been deprecated

Using the following commands and options in RHEL 8 Kickstart files will print a warning in the logs:

- `auth` or `authconfig`
- `device`
- `deviceprobe`
- `dmraid`
- `install`
- `lilo`
- `lilocheck`
- `mouse`
- `multipath`
- `bootloader --upgrade`
- `ignoredisk --interactive`
- `partition --active`
- `reboot --kexec`
Where only specific options are listed, the base command and its other options are still available and not deprecated.

For more details and related changes in Kickstart, see the Kickstart changes section of the Considerations in adopting RHEL 8 document.

(BZ#1642765)

**The --interactive option of the ignoredisk Kickstart command has been deprecated**

Using the **--interactive option** in future releases of Red Hat Enterprise Linux will result in a fatal installation error. It is recommended that you modify your Kickstart file to remove the option.

(BZ#1637872)

**The Kickstart autostep command has been deprecated**

The **autostep** command has been deprecated. The related section about this command has been removed from the RHEL 8 documentation.

(BZ#1904251)

### 7.2. SOFTWARE MANAGEMENT

**rpmbuild --sign is deprecated**

The **rpmbuild --sign** command is deprecated since RHEL 8.1. Using this command in future releases of Red Hat Enterprise Linux can result in an error. It is recommended that you use the **rpmsign** command instead.

(BZ#1688849)

### 7.3. SHELLS AND COMMAND-LINE TOOLS

**The OpenEXR component has been deprecated**

The **OpenEXR** component has been deprecated. Hence, the support for the **EXR** image format has been dropped from the **imagecodecs** module.

(BZ#1886310)

**The dump utility from the dump package has been deprecated**

The **dump** utility used for backup of file systems has been deprecated and will not be available in RHEL 9.

In RHEL 9, Red Hat recommends using the **tar, dd, or bacula**, backup utility, based on type of usage, which provides full and safe backups on ext2, ext3, and ext4 file systems.

Note that the **restore** utility from the **dump** package remains available and supported in RHEL 9 and is available as the **restore** package.

(BZ#1997366)

**The ABRT tool has been deprecated**
The Automatic Bug Reporting Tool (ABRT) for detecting and reporting application crashes has been deprecated in RHEL 8. As a replacement, use the `systemd-coredump` tool to log and store core dumps, which are automatically generated files after a program crashes.

(BZ#2055826)

**The ReaR crontab has been deprecated**

The `/etc/cron.d/rear` crontab from the `rear` package has been deprecated in RHEL 8 and will not be available in RHEL 9. The crontab checks every night whether the disk layout has changed, and runs `rear mkrescue` command if a change happened.

If you require this functionality, after an upgrade to RHEL 9, configure periodic runs of ReaR manually.

(BZ#2083301)

**The hidepid=n mount option is not supported in RHEL 8 · systemd**

The mount option `hidepid=n`, which controls who can access information in `/proc/[pid]` directories, is not compatible with `systemd` infrastructure provided in RHEL 8.

In addition, using this option might cause certain services started by `systemd` to produce SELinux AVC denial messages and prevent other operations from completing.

For more information, see the related Is mounting `/proc` with "hidepid=2" recommended with RHEL7 and RHEL8?.

(BZ#2038929)

**The `/usr/lib/udev/rename_device` utility has been deprecated**

The `udev` helper utility `/usr/lib/udev/rename_device` for renaming network interfaces has been deprecated.

(BZ#1875485)

### 7.4. SECURITY

**NSS SEED ciphers are deprecated**

The Mozilla Network Security Services (NSS) library will not support TLS cipher suites that use a SEED cipher in a future release. To ensure smooth transition of deployments that rely on SEED ciphers when NSS removes support, Red Hat recommends enabling support for other cipher suites.

Note that SEED ciphers are already disabled by default in RHEL.

(BZ#1817533)

**TLS 1.0 and TLS 1.1 are deprecated**

The TLS 1.0 and TLS 1.1 protocols are disabled in the DEFAULT system-wide cryptographic policy level. If your scenario, for example, a video conferencing application in the Firefox web browser, requires using the deprecated protocols, switch the system-wide cryptographic policy to the LEGACY level:

```
# update-crypto-policies --set LEGACY
```
For more information, see the Strong crypto defaults in RHEL 8 and deprecation of weak crypto algorithms Knowledgebase article on the Red Hat Customer Portal and the update-crypto-policies(8) man page.

(BZ#1660839)

DSA is deprecated in RHEL 8

The Digital Signature Algorithm (DSA) is considered deprecated in Red Hat Enterprise Linux 8. Authentication mechanisms that depend on DSA keys do not work in the default configuration. Note that OpenSSH clients do not accept DSA host keys even in the LEGACY system-wide cryptographic policy level.

(BZ#1646541)

SSL2 Client Hello has been deprecated in NSS

The Transport Layer Security (TLS) protocol version 1.2 and earlier allow to start a negotiation with a Client Hello message formatted in a way that is backward compatible with the Secure Sockets Layer (SSL) protocol version 2. Support for this feature in the Network Security Services (NSS) library has been deprecated and it is disabled by default.

Applications that require support for this feature need to use the new SSL_ENABLE_V2_COMPATIBLE_HELLO API to enable it. Support for this feature may be removed completely in future releases of Red Hat Enterprise Linux 8.

(BZ#1645153)

TPM 1.2 is deprecated

The Trusted Platform Module (TPM) secure cryptoprocessor standard version was updated to version 2.0 in 2016. TPM 2.0 provides many improvements over TPM 1.2, and it is not backward compatible with the previous version. TPM 1.2 is deprecated in RHEL 8, and it might be removed in the next major release.

(BZ#1657927)

crypto-policies derived properties are now deprecated

With the introduction of scopes for crypto-policies directives in custom policies, the following derived properties have been deprecated: tls_cipher, ssh_cipher, ssh_group, ike_protocol, and sha1_in_dnssec. Additionally, the use of the protocol property without specifying a scope is now deprecated as well. See the crypto-policies(7) man page for recommended replacements.

(BZ#2011208)

Runtime disabling SELinux using /etc/selinux/config is now deprecated

Runtime disabling SELinux using the SELINUX=disabled option in the /etc/selinux/config file has been deprecated. In RHEL 9, when you disable SELinux only through /etc/selinux/config, the system starts with SELinux enabled but with no policy loaded.

If your scenario really requires to completely disable SELinux, Red Hat recommends disabling SELinux by adding the selinux=0 parameter to the kernel command line as described in the Changing SELinux modes at boot time section of the Using SELinux title.

(BZ#1932222)

The ipa SELinux module removed from selinux-policy
The **ipa** SELinux module has been removed from the **selinux-policy** package because it is no longer maintained. The functionality is now included in the **ipa-selinux** subpackage.

If your scenario requires the use of types or interfaces from the **ipa** module in a local SELinux policy, install the **ipa-selinux** package.

(BZ#1461914)

**fapolicyd.rules is deprecated**

The `/etc/fapolicyd/rules.d/` directory for files containing allow and deny execution rules replaces the `/etc/fapolicyd/fapolicyd.rules` file. The **fagenrules** script now merges all component rule files in this directory to the `/etc/fapolicyd/compiled.rules` file. Rules in `/etc/fapolicyd/fapolicyd.trust` are still processed by the **fapolicyd** framework but only for ensuring backward compatibility.

(BZ#2054741)

### 7.5. NETWORKING

**Network scripts are deprecated in RHEL 8**

Network scripts are deprecated in Red Hat Enterprise Linux 8 and they are no longer provided by default. The basic installation provides a new version of the **ifup** and **ifdown** scripts which call the NetworkManager service through the **nmcli** tool. In Red Hat Enterprise Linux 8, to run the **ifup** and the **ifdown** scripts, NetworkManager must be running.

Note that custom commands in `/sbin/ifup-local, ifdown-pre-local` and **ifdown-local** scripts are not executed.

If any of these scripts are required, the installation of the deprecated network scripts in the system is still possible with the following command:

```
~]# yum install network-scripts
```

The **ifup** and **ifdown** scripts link to the installed legacy network scripts.

Calling the legacy network scripts shows a warning about their deprecation.

(BZ#1647725)

**The dropwatch tool is deprecated**

The **dropwatch** tool has been deprecated. The tool will not be supported in future releases, thus it is not recommended for new deployments. As a replacement of this package, Red Hat recommends to use the **perf** command line tool.

For more information on using the **perf** command line tool, see the **Getting started with Perf** section on the Red Hat customer portal or the **perf** man page.

(BZ#1929173)

**The cgdcbxd package is deprecated**

Control group data center bridging exchange daemon (**cgdcbxd**) is a service to monitor data center bridging (DCB) netlink events and manage the **net_prio control** group subsystem. Starting with RHEL 8.5, the **cgdcbxd** package is deprecated and will be removed in the next major RHEL release.
The `xinetd` service has been deprecated

The `xinetd` service has been deprecated and will be removed in RHEL 9. As a replacement, use `systemd`. For further details, see How to convert xinetd service to systemd.

The WEP Wi-Fi connection method is deprecated

The insecure wired equivalent privacy (WEP) Wi-Fi connection method is deprecated in RHEL 8.6 and will be removed in RHEL 9.0. For secure Wi-Fi connections, use the Wi-Fi Protected Access 3 (WPA3) or WPA2 connection methods.

The unsupported `xt_u32` module is now deprecated

Using the unsupported `xt_u32` module, users of `iptables` can match arbitrary 32 bits in the packet header or payload. In RHEL 8.6, the `xt_u32` module is deprecated and will be removed in RHEL 9.

If you use `xt_u32`, migrate to the `nftables` packet filtering framework. For example, first change your firewall to use `iptables` with native matches to incrementally replace individual rules, and later use the `iptables-translate` and accompanying utilities to migrate to `nftables`. If no native match exists in `nftables`, use the raw payload matching feature of `nftables`. For details, see the raw payload expression section in the `nft(8)` man page.

Kernel live patching now covers all RHEL minor releases

Since RHEL 8.1, kernel live patches have been provided for selected minor release streams of RHEL covered under the Extended Update Support (EUS) policy to remediate Critical and Important Common Vulnerabilities and Exposures (CVEs). To accommodate the maximum number of concurrently covered kernels and use cases, the support window for each live patch will be decreased from 12 to 6 months for every minor, major and zStream version of the kernel. It means that on the day a kernel live patch is released, it will cover every minor release and scheduled errata kernel delivered in the past 6 months. For example, 8.4.x will have a one-year support window, but 8.4.x+1 will have 6 months.

For more information about this feature, see Applying patches with kernel live patching.

For details about available kernel live patches, see Kernel Live Patch life cycles.

Installing RHEL for Real Time 8 using diskless boot is now deprecated

Diskless booting allows multiple systems to share a root file system through the network. While convenient, diskless boot is prone to introducing network latency in real-time workloads. With a future minor update of RHEL for Real Time 8, the diskless booting feature will no longer be supported.

The Linux `firewire` sub-system and its associated user-space components are deprecated in RHEL 8
The **firewire** sub-system provides interfaces to use and maintain any resources on the IEEE 1394 bus. In RHEL 9, **firewire** will no longer be supported in the **kernel** package. Note that **firewire** contains several user-space components provided by the **libavc1394**, **libdc1394**, **libraw1394** packages. These packages are subject to the deprecation as well.

(BZ#1871863)

The **rdma_rxe** Soft-RoCE driver is deprecated

Software Remote Direct Memory Access over Converged Ethernet (Soft-RoCE), also known as RXE, is a feature that emulates Remote Direct Memory Access (RDMA). In RHEL 8, the Soft-RoCE feature is available as an unsupported Technology Preview. However, due to stability issues, this feature has been deprecated and will be removed in RHEL 9.

(BZ#1878207)

### 7.7. FILE SYSTEMS AND STORAGE

#### VDO write modes other than async are deprecated

VDO supports several write modes in RHEL 8:

- **sync**
- **async**
- **async-unsafe**
- **auto**

Starting with RHEL 8.4, the following write modes are deprecated:

**sync**

Devices above the VDO layer cannot recognize if VDO is synchronous, and consequently, the devices cannot take advantage of the VDO **sync** mode.

**async-unsafe**

VDO added this write mode as a workaround for the reduced performance of **async** mode, which complies to Atomicity, Consistency, Isolation, and Durability (ACID). Red Hat does not recommend **async-unsafe** for most use cases and is not aware of any users who rely on it.

**auto**

This write mode only selects one of the other write modes. It is no longer necessary when VDO supports only a single write mode.

These write modes will be removed in a future major RHEL release.

The recommended VDO write mode is now **async**.

For more information on VDO write modes, see Selecting a VDO write mode.

(JIRA:RHELPLAN-70700)

#### NFSv3 over UDP has been disabled

The NFS server no longer opens or listens on a User Datagram Protocol (UDP) socket by default. This change affects only NFS version 3 because version 4 requires the Transmission Control Protocol (TCP).
NFS over UDP is no longer supported in RHEL 8.

(BZ#1592011)

**cramfs has been deprecated**

Due to lack of users, the **cramfs** kernel module is deprecated. **squashfs** is recommended as an alternative solution.

(BZ#1794513)

**VDO manager has been deprecated**

The python-based VDO management software has been deprecated and will be removed from RHEL 9. In RHEL 9, it will be replaced by the LVM-VDO integration. Therefore, it is recommended to create VDO volumes using the **lvcreate** command.

The existing volumes created using the VDO management software can be converted using the **/usr/sbin/lvm_import_vdo** script, provided by the **lvm2** package. For more information on the LVM-VDO implementation, see [Deduplicating and compressing logical volumes on RHEL](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html/deduplicating_and_compressing_logical_volumes_on_rhel).  

(BZ#1949163)

**The elevator kernel command line parameter is deprecated**

The **elevator** kernel command line parameter was used in earlier RHEL releases to set the disk scheduler for all devices. In RHEL 8, the parameter is deprecated.

The upstream Linux kernel has removed support for the **elevator** parameter, but it is still available in RHEL 8 for compatibility reasons.

Note that the kernel selects a default disk scheduler based on the type of device. This is typically the optimal setting. If you require a different scheduler, Red Hat recommends that you use **udev** rules or the TuneD service to configure it. Match the selected devices and switch the scheduler only for those devices.

For more information, see [Setting the disk scheduler](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html/deduplicating_and_compressing_logical_volumes_on_rhel).  

(BZ#1665295)

**LVM mirror is deprecated**

The LVM **mirror** segment type is now deprecated. Support for **mirror** will be removed in a future major release of RHEL.

Red Hat recommends that you use LVM RAID 1 devices with a segment type of **raid1** instead of **mirror**. The **raid1** segment type is the default RAID configuration type and replaces **mirror** as the recommended solution.

To convert **mirror** devices to **raid1**, see [Converting a mirrored LVM device to a RAID1 device](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html/deduplicating_and_compressing_logical_volumes_on_rhel).

LVM **mirror** has several known issues. For details, see [known issues in file systems and storage](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html/deduplicating_and_compressing_logical_volumes_on_rhel).  

(BZ#1827628)

**peripety is deprecated**

The **peripety** package is deprecated since RHEL 8.3.
The Peripety storage event notification daemon parses system storage logs into structured storage events. It helps you investigate storage issues.

(BZ#1871953)

7.8. HIGH AVAILABILITY AND CLUSTERS

**pcs commands that support the clufter tool have been deprecated**

The **pcs** commands that support the **clufter** tool for analyzing cluster configuration formats have been deprecated. These commands now print a warning that the command has been deprecated and sections related to these commands have been removed from the **pcs** help display and the **pcs(8)** man page.

The following commands have been deprecated:

- **pcs config import-cman** for importing CMAN / RHEL6 HA cluster configuration
- **pcs config export** for exporting cluster configuration to a list of **pcs** commands which recreate the same cluster

(BZ#1851335)

7.9. COMPILERS AND DEVELOPMENT TOOLS

**libdwarf has been deprecated**

The **libdwarf** library has been deprecated in RHEL 8. The library will likely not be supported in future major releases. Instead, use the **elfutils** and **libdw** libraries for applications that wish to process ELF/DWARF files.

Alternatives for the **libdwarf-tools dwarfdump** program are the **binutils readelf** program or the **elfutils eu-readelf** program, both used by passing the **--debug-dump** flag.

(BZ#1920624)

**The gdb.i686 packages are deprecated**

In RHEL 8.1, the 32-bit versions of the GNU Debugger (GDB), **gdb.i686**, were shipped due to a dependency problem in another package. Because RHEL 8 does not support 32-bit hardware, the **gdb.i686** packages are deprecated since RHEL 8.4. The 64-bit versions of GDB, **gdb.x86_64**, are fully capable of debugging 32-bit applications.

If you use **gdb.i686**, note the following important issues:

- The **gdb.i686** packages will no longer be updated. Users must install **gdb.x86_64** instead.
- If you have **gdb.i686** installed, installing **gdb.x86_64** will cause **dnf** to report package **gdb-8.2-14.el8.x86_64** obsoletes gdb < 8.2-12.el8 provided by **gdb-8.2-12.el8.i686**. This is expected. Either uninstall **gdb.i686** or pass **dnf** the **--allowerasing** option to remove **gdb.i686** and install **gdb.x86_64**.
- Users will no longer be able to install the **gdb.i686** packages on 64-bit systems, that is, those with the **libc.so.6()(64-bit)** packages.

(BZ#1853140)
7.10. IDENTITY MANAGEMENT

**openssh-ldap has been deprecated**

The **openssh-ldap** subpackage has been deprecated in Red Hat Enterprise Linux 8 and will be removed in RHEL 9. As the **openssh-ldap** subpackage is not maintained upstream, Red Hat recommends using SSSD and the **sss_ssh Authorizedkeys** helper, which integrate better with other IdM solutions and are more secure.

By default, the SSSD **ldap** and **ipa** providers read the **sshPublicKey** LDAP attribute of the user object, if available. Note that you cannot use the default SSSD configuration for the **ad** provider or IdM trusted domains to retrieve SSH public keys from Active Directory (AD), since AD does not have a default LDAP attribute to store a public key.

To allow the **sss_ssh Authorizedkeys** helper to get the key from SSSD, enable the **ssh** responder by adding **ssh** to the **services** option in the **sssd.conf** file. See the **sssd.conf(5)** man page for details.

To allow **sshd** to use **sss_ssh Authorizedkeys**, add the **AuthorizedKeysCommand** /usr/bin/sss_ssh Authorizedkeys and **AuthorizedKeysCommandUser nobody** options to the /etc/ssh/sshd_config file as described by the **sss_ssh Authorizedkeys(1)** man page.

(BZ#1871025)

**DES and 3DES encryption types have been removed**

Due to security reasons, the Data Encryption Standard (DES) algorithm has been deprecated and disabled by default since RHEL 7. With the recent rebase of Kerberos packages, single-DES (DES) and triple-DES (3DES) encryption types have been removed from RHEL 8.

If you have configured services or users to only use DES or 3DES encryption, you might experience service interruptions such as:

- Kerberos authentication errors
- **unknown enctype** encryption errors
- Kerberos Distribution Centers (KDCs) with DES-encrypted Database Master Keys (**K/M**) fail to start

Perform the following actions to prepare for the upgrade:

1. Check if your KDC uses DES or 3DES encryption with the **krb5check** open source Python scripts. See krb5check on GitHub.

2. If you are using DES or 3DES encryption with any Kerberos principals, re-key them with a supported encryption type, such as Advanced Encryption Standard (AES). For instructions on re-keying, see Retiring DES from MIT Kerberos Documentation.

3. Test independence from DES and 3DES by temporarily setting the following Kerberos options before upgrading:
   a. In /var/kerberos/krb5kdc/kdc.conf on the KDC, set **supported_enctypes** and do not include des or des3.
   b. For every host, in /etc/krb5.conf and any files in /etc/krb5.conf.d, set **allow_weak_crypto** to false. It is false by default.
c. For every host, in `/etc/krb5.conf` and any files in `/etc/krb5.conf.d`, set `permitted_enctypes`, `default_tgs_enctypes`, and `default_tkt_enctypes`, and do not include `des` or `des3`.

4. If you do not experience any service interruptions with the test Kerberos settings from the previous step, remove them and upgrade. You do not need those settings after upgrading to the latest Kerberos packages.

(BZ#1877991)

**Standalone use of the ctdb service has been deprecated**

Since RHEL 8.4, customers are advised to use the ctdb clustered Samba service only when both of the following conditions apply:

- The ctdb service is managed as a *pacemaker* resource with the resource-agent *ctdb*.
- The ctdb service uses storage volumes that contain either a GlusterFS file system provided by the Red Hat Gluster Storage product or a GFS2 file system.

The stand-alone use case of the ctdb service has been deprecated and will not be included in a next major release of Red Hat Enterprise Linux. For further information on support policies for Samba, see the Knowledgebase article [Support Policies for RHEL Resilient Storage - ctdb General Policies](#).

(BZ#1916296)

**Running Samba as a PDC or BDC is deprecated**

The classic domain controller mode that enabled administrators to run Samba as an NT4-like primary domain controller (PDC) and backup domain controller (BDC) is deprecated. The code and settings to configure these modes will be removed in a future Samba release.

As long as the Samba version in RHEL 8 provides the PDC and BDC modes, Red Hat supports these modes only in existing installations with Windows versions which support NT4 domains. Red Hat recommends not setting up a new Samba NT4 domain, because Microsoft operating systems later than Windows 7 and Windows Server 2008 R2 do not support NT4 domains.

If you use the PDC to authenticate only Linux users, Red Hat suggests migrating to Red Hat Identity Management (IdM) that is included in RHEL subscriptions. However, you cannot join Windows systems to an IdM domain. Note that Red Hat continues supporting the PDC functionality IdM uses in the background.

Red Hat does not support running Samba as an AD domain controller (DC).

(BZ#1926114)

**Indirect AD integration with IdM via WinSync has been deprecated**

WinSync is no longer actively developed in RHEL 8 due to several functional limitations:

- WinSync supports only one Active Directory (AD) domain.
- Password synchronization requires installing additional software on AD Domain Controllers.

For a more robust solution with better resource and security separation, Red Hat recommends using a *cross-forest trust* for indirect integration with Active Directory. See the Indirect integration documentation.

(JIRA:RHELPLAN-100400)
The SSSD version of libwbclient has been removed

The SSSD implementation of the libwbclient package was deprecated in RHEL 8.4. As it cannot be used with recent versions of Samba, the SSSD implementation of libwbclient has now been removed.

(BZ#1947671)

7.11. DESKTOP

The libgnome-keyring library has been deprecated

The libgnome-keyring library has been deprecated in favor of the libsecret library, as libgnome-keyring is not maintained upstream, and does not follow the necessary cryptographic policies for RHEL. The new libsecret library is the replacement that follows the necessary security standards.

(BZ#1607766)

The kernelopts environment variable has been deprecated

In RHEL 8, the kernel command-line parameters for systems using the GRUB2 bootloader were defined in the kernelopts environment variable. The variable was stored in the /boot/grub2/grubenv file for each kernel boot entry. However, storing the kernel command-line parameters using kernelopts was not robust. Therefore, with a future major update of RHEL, kernelopts will be removed and the kernel command-line parameters will be stored in the Boot Loader Specification (BLS) snippet instead.

(BZ#2060759)

7.12. GRAPHICS INFRASTRUCTURES

AGP graphics cards are no longer supported

Graphics cards using the Accelerated Graphics Port (AGP) bus are not supported in Red Hat Enterprise Linux 8. Use the graphics cards with PCI-Express bus as the recommended replacement.

(BZ#1569610)

Motif has been deprecated

The Motif widget toolkit has been deprecated in RHEL, because development in the upstream Motif community is inactive.

The following Motif packages have been deprecated, including their development and debugging variants:

- motif
- openmotif
- openmotif21
- openmotif22

Additionally, the motif-static package has been removed.

Red Hat recommends using the GTK toolkit as a replacement. GTK is more maintainable and provides new features compared to Motif.
7.13. THE WEB CONSOLE

The web console no longer supports incomplete translations

The RHEL web console no longer provides translations for languages that have translations available for less than 50% of the Console’s translatable strings. If the browser requests translation to such a language, the user interface will be in English instead.

(BZ#1666722)

7.14. RED HAT ENTERPRISE LINUX SYSTEM ROLES

The networking System Role displays a deprecation warning when configuring teams on RHEL 9 nodes

The network teaming capabilities have been deprecated in RHEL 9. As a result, using the networking RHEL System Role on an RHEL 8 controller to configure a network team on RHEL 9 nodes, shows a warning about its deprecation.

(BZ#2021685)

Ansible Engine has been deprecated

Previous versions of RHEL 8 provided access to an Ansible Engine repository, with a limited scope of support, to enable supported RHEL Automation use cases, such as RHEL System Roles and Insights remediations. Ansible Engine has been deprecated, and Ansible Engine 2.9 will have no support after September 29, 2023. For more details on the supported use cases, see Scope of support for the Ansible Core package included in the RHEL 9 AppStream.

Users must manually migrate their systems from Ansible Engine to Ansible Core. For that, follow the steps:

Procedure

1. Check if the system is running RHEL 8.6:
   
   ```bash
   # cat /etc/redhat-release
   ```

2. Uninstall Ansible Engine 2.9:
   
   ```bash
   # yum remove ansible
   ```

3. Disable the ansible-2-for-rhel-8-x86_64-rpms repository:

   ```bash
   # subscription-manager repos --disable ansible-2-for-rhel-8-x86_64-rpms
   ```

4. Install the Ansible Core package from the RHEL 8 AppStream repository:

   ```bash
   # yum install ansible-core
   ```

For more details, see: Using Ansible in RHEL 8.6 and later.
The **geoipupdate** package has been deprecated

The **geoipupdate** package requires a third-party subscription and it also downloads proprietary content. Therefore, the **geoipupdate** package has been deprecated, and will be removed in the next major RHEL version.

(vBZ#1874892)

7.15. VIRTUALIZATION

**virsh iface-** commands have become deprecated

The **virsh iface-** commands, such as **virsh iface-start** and **virsh iface-destroy**, are now deprecated, and will be removed in a future major version of RHEL. In addition, these commands frequently fail due to configuration dependencies.

Therefore, it is recommended not to use **virsh iface-** commands for configuring and managing host network connections. Instead, use the NetworkManager program and its related management applications, such as **nmcli**.

(BZ#1664592)

**virt-manager has been deprecated**

The Virtual Machine Manager application, also known as **virt-manager**, has been deprecated. The RHEL web console, also known as **Cockpit**, is intended to become its replacement in a subsequent release. It is, therefore, recommended that you use the web console for managing virtualization in a GUI. Note, however, that some features available in **virt-manager** may not be yet available in the RHEL web console.

(JIRA:RHELPLAN-10304)

**Virtual machine snapshots are not properly supported in RHEL 8**

The current mechanism of creating virtual machine (VM) snapshots has been deprecated, as it is not working reliably. As a consequence, it is recommended not to use VM snapshots in RHEL 8.

(BZ#1686057)

**The Cirrus VGA virtual GPU type has been deprecated**

With a future major update of Red Hat Enterprise Linux, the **Cirrus VGA** GPU device will no longer be supported in KVM virtual machines. Therefore, Red Hat recommends using the **stdvga**, **virtio-vga**, or **qxl** devices instead of **Cirrus VGA**.

(BZ#1651994)

**KVM on IBM POWER has been deprecated**

Using KVM virtualization on IBM POWER hardware has become deprecated. As a result, KVM on IBM POWER is still supported in RHEL 8, but will become unsupported in a future major release of RHEL.

(JIRA:RHELPLAN-71200)

**SecureBoot image verification using SHA1-based signatures is deprecated**
Performing SecureBoot image verification using SHA1-based signatures on UEFI (PE/COFF) executables has become deprecated. Instead, Red Hat recommends using signatures based on the SHA2 algorithm, or later.

(BZ#1935497)

Using SPICE to attach smart card readers to virtual machines has been deprecated

The SPICE remote display protocol has been deprecated in RHEL 8. Since the only recommended way to attach smart card readers to virtual machines (VMs) depends on the SPICE protocol, the usage of smart cards in VMs has also become deprecated in RHEL 8.

In a future major version of RHEL, the functionality of attaching smart card readers to VMs will only be supported by third party remote visualization solutions.

(BZ#2059626)

SPICE has been deprecated

The SPICE remote display protocol has become deprecated. Note that SPICE will remain supported in RHEL 8, but Red Hat recommends using alternate solutions for remote display streaming:

- For remote console access, use the VNC protocol.
- For advanced remote display functions, use third party tools such as RDP, HP RGS, or Mechdyne TGX.

(BZ#1849563)

7.16. CONTAINERS

The Podman varlink-based API v1.0 has been removed

The Podman varlink-based API v1.0 was deprecated in a previous release of RHEL 8. Podman v2.0 introduced a new Podman v2.0 RESTful API. With the release of Podman v3.0, the varlink-based API v1.0 has been completely removed.

(JIRA:RHELPLAN-45858)

container-tools:1.0 has been deprecated

The container-tools:1.0 module has been deprecated and will no longer receive security updates. It is recommended to use a newer supported stable module stream, such as container-tools:2.0 or container-tools:3.0.

(JIRA:RHELPLAN-59825)

The container-tools:2.0 module has been deprecated

The container-tools:2.0 module has been deprecated and will no longer receive security updates. It is recommended to use a newer supported stable module stream, such as container-tools:3.0.

(JIRA:RHELPLAN-85066)

7.17. DEPRECATED PACKAGES

This section lists packages that have been deprecated and will probably not be included in a future major release of Red Hat Enterprise Linux.
For changes to packages between RHEL 7 and RHEL 8, see Changes to packages in the Considerations in adopting RHEL 8 document.

The following packages have been deprecated and remain supported until the end of life of RHEL 8:

- 389-ds-base-legacy-tools
- abrt
- abrt-addon-ccpp
- abrt-addon-kerneloops
- abrt-addon-pstoreoops
- abrt-addon-vmcore
- abrt-addon-xorg
- abrt-cli

CHAPTER 7. DEPRECATED FUNCTIONALITY
7.18. DEPRECATED AND UNMAINTAINED DEVICES

This section lists devices (drivers, adapters) that
• continue to be supported until the end of life of RHEL 8 but will likely not be supported in future major releases of this product and are not recommended for new deployments. Support for devices other than those listed remains unchanged. These are deprecated devices.

• are available but are no longer being tested or updated on a routine basis in RHEL 8. Red Hat may fix serious bugs, including security bugs, at its discretion. These devices should no longer be used in production, and it is likely they will be disabled in the next major release. These are unmaintained devices.

PCI device IDs are in the format of vendor:device:subvendor:subdevice. If no device ID is listed, all devices associated with the corresponding driver have been deprecated. To check the PCI IDs of the hardware on your system, run the `lspci -nn` command.

[a] Disabled in RHEL 8.0, re-enabled in RHEL 8.4 due to customer requests.
CHAPTER 8. KNOWN ISSUES

This part describes known issues in Red Hat Enterprise Linux 8.6.

8.1. INSTALLER AND IMAGE CREATION

Installation fails on IBM Power 10 systems with LPAR and secure boot enabled

RHEL installer is not integrated with static key secure boot on IBM Power 10 systems. Consequently, when logical partition (LPAR) is enabled with the secure boot option, the installation fails with the error, Unable to proceed with RHEL-x.x Installation.

To work around this problem, install RHEL without enabling secure boot. After booting the system:

1. Copy the signed Kernel into the PReP partition using the `dd` command.
2. Restart the system and enable secure boot.

Once the firmware verifies the bootloader and the kernel, the system boots up successfully.

For more information, see https://www.ibm.com/support/pages/node/6528884

(BZ#2025814)

Unexpected SELinux policies on systems where Anaconda is running as an application

When Anaconda is running as an application on an already installed system (for example to perform another installation to an image file using the `--image` anaconda option), the system is not prohibited to modify the SELinux types and attributes during installation. As a consequence, certain elements of SELinux policy might change on the system where Anaconda is running. To work around this problem, do not run Anaconda on the production system and execute it in a temporary virtual machine. So that the SELinux policy on a production system is not modified. Running anaconda as part of the system installation process such as installing from `boot.iso` or `dvd.iso` is not affected by this issue.

(BZ#2050140)

The auth and authconfig Kickstart commands require the AppStream repository

The `authselect-compat` package is required by the `auth` and `authconfig` Kickstart commands during installation. Without this package, the installation fails if `auth` or `authconfig` are used. However, by design, the `authselect-compat` package is only available in the AppStream repository.

To work around this problem, verify that the BaseOS and AppStream repositories are available to the installer or use the `authselect` Kickstart command during installation.

(BZ#1640697)

The reboot --kexec and inst.kexec commands do not provide a predictable system state

Performing a RHEL installation with the `reboot --kexec` Kickstart command or the `inst.kexec` kernel boot parameters do not provide the same predictable system state as a full reboot. As a consequence, switching to the installed system without rebooting can produce unpredictable results.

Note that the `kexec` feature is deprecated and will be removed in a future release of Red Hat Enterprise Linux.

(BZ#1697896)
The USB CD-ROM drive is not available as an installation source in Anaconda

Installation fails when the USB CD-ROM drive is the source for it and the Kickstart `ignoredisk --only-use=` command is specified. In this case, Anaconda cannot find and use this source disk.

To work around this problem, use the `harddrive --partition=sdX --dir=/` command to install from USB CD-ROM drive. As a result, the installation does not fail.

(BZ#1914955)

Network access is not enabled by default in the installation program

Several installation features require network access, for example, registration of a system using the Content Delivery Network (CDN), NTP server support, and network installation sources. However, network access is not enabled by default, and as a result, these features cannot be used until network access is enabled.

To work around this problem, add `ip=dhcp` to boot options to enable network access when the installation starts. Optionally, passing a Kickstart file or a repository located on the network using boot options also resolves the problem. As a result, the network-based installation features can be used.

(BZ#1757877)

Hard drive partitioned installations with iso9660 filesystem fails

You cannot install RHEL on systems where the hard drive is partitioned with the iso9660 filesystem. This is due to the updated installation code that is set to ignore any hard disk containing a iso9660 file system partition. This happens even when RHEL is installed without using a DVD.

To workaround this problem, add the following script in the kickstart file to format the disc before the installation starts.

Note: Before performing the workaround, backup the data available on the disk. The `wipefs` command formats all the existing data from the disk.

```
%pre
    wipefs -a /dev/sda
%end
```

As a result, installations work as expected without any errors.

(BZ#1929105)

IBM Power systems with HASH MMU mode fail to boot with memory allocation failures

IBM Power Systems with HASH memory allocation unit (MMU) mode support kdump up to a maximum of 192 cores. Consequently, the system fails to boot with memory allocation failures if kdump is enabled on more than 192 cores. This limitation is due to RMA memory allocations during early boot in HASH MMU mode. To work around this problem, use the Radix MMU mode with fadump enabled instead of using kdump.

(BZ#2028361)

8.2. SUBSCRIPTION MANAGEMENT

syspurpose addons have no effect on the subscription-manager attach --auto output.
In Red Hat Enterprise Linux 8, four attributes of the `syspurpose` command-line tool have been added: `role`, `usage`, `service_level_agreement` and `addons`. Currently, only `role`, `usage` and `service_level_agreement` affect the output of running the `subscription-manager attach --auto` command. Users who attempt to set values to the `addons` argument will not observe any effect on the subscriptions that are auto-attached.

(BZ#1687900)

### 8.3. SOFTWARE MANAGEMENT

**cr_compress_file_with_stat() can cause a memory leak**

The `creatorepo_c` C library has the API `cr_compress_file_with_stat()` function. This function is declared with `char **dst` as a second parameter. Depending on its other parameters, `cr_compress_file_with_stat()` either uses `dst` as an input parameter, or uses it to return an allocated string. This unpredictable behavior can cause a memory leak, because it does not inform the user when to free `dst` contents.

To work around this problem, a new API `cr_compress_file_with_stat_v2` function has been added, which uses the `dst` parameter only as an input. It is declared as `char *dst`. This prevents memory leak.

Note that the `cr_compress_file_with_stat_v2` function is temporary and will be present only in RHEL 8. Later, `cr_compress_file_with_stat()` will be fixed instead.

(BZ#1973588)

**YUM transactions reported as successful when a scriptlet fails**

Since RPM version 4.6, post-install scriptlets are allowed to fail without being fatal to the transaction. This behavior propagates up to YUM as well. This results in scriptlets which might occasionally fail while the overall package transaction reports as successful.

There is no workaround available at the moment.

Note that this is expected behavior that remains consistent between RPM and YUM. Any issues in scriptlets should be addressed at the package level.

(BZ#1986657)

### 8.4. SHELLS AND COMMAND-LINE TOOLS

**coreutils might report misleading EPERM error codes**

GNU Core Utilities (`coreutils`) started using the `statx()` system call. If a `seccomp` filter returns an EPERM error code for unknown system calls, `coreutils` might consequently report misleading EPERM error codes because EPERM cannot be distinguished from the actual `Operation not permitted` error returned by a working `statx()` syscall.

To work around this problem, update the `seccomp` filter to either permit the `statx()` syscall, or to return an ENOSYS error code for syscalls it does not know.

(BZ#2030661)

### 8.5. INFRASTRUCTURE SERVICES

**Postfix TLS fingerprint algorithm in the FIPS mode needs to be changed to SHA-256**
By default in RHEL 8, **postfix** uses MD5 fingerprints with the TLS for backward compatibility. But in the FIPS mode, the MD5 hashing function is not available, which may cause TLS to incorrectly function in the default postfix configuration. To workaroud this problem, the hashing function needs to be changed to SHA-256 in the postfix configuration file.

For more details, see the related Knowledgebase article *Fix postfix TLS in the FIPS mode by switching to SHA-256 instead of MD5*.

(BZ#1711885)

**The brltty package is not multilib compatible**

It is not possible to have both 32-bit and 64-bit versions of the **brltty** package installed. You can either install the 32-bit (**brltty.i686**) or the 64-bit (**brltty.x86_64**) version of the package. The 64-bit version is recommended.

(BZ#2008197)

### 8.6. SECURITY

**File permissions of /etc/passwd- are not aligned with the CIS RHEL 8 Benchmark 1.0.0**

Because of an issue with the CIS Benchmark, the remediation of the SCAP rule that ensures permissions on the /etc/passwd- backup file configures permissions to **0644**. However, the **CIS Red Hat Enterprise Linux 8 Benchmark 1.0.0** requires file permissions **0600** for that file. As a consequence, the file permissions of /etc/passwd- are not aligned with the benchmark after remediation.

(BZ#1858866)

**libselinux-python is available only through its module**

The **libselinux-python** package contains only Python 2 bindings for developing SELinux applications and it is used for backward compatibility. For this reason, **libselinux-python** is no longer available in the default RHEL 8 repositories through the `yum install libselinux-python` command.

To work around this problem, enable both the **libselinux-python** and **python27** modules, and install the **libselinux-python** package and its dependencies with the following commands:

```
# yum module enable libselinux-python
# yum install libselinux-python
```

Alternatively, install **libselinux-python** using its install profile with a single command:

```
# yum module install libselinux-python:2.8/common
```

As a result, you can install **libselinux-python** using the respective module.

(BZ#1666328)

**udica processes UBI 8 containers only when started with --env container=podman**

The Red Hat Universal Base Image 8 (*UBI 8*) containers set the **container** environment variable to the **oci** value instead of the **podman** value. This prevents the **udica** tool from analyzing a container JavaScript Object Notation (JSON) file.
To work around this problem, start a UBI 8 container using a `podman` command with the `--env container=podman` parameter. As a result, `udica` can generate an SELinux policy for a UBI 8 container only when you use the described workaround.

(BZ#1763210)

**SELINUX=disabled in /etc/selinux/config does not work properly**

Disabling SELinux using the `SELINUX=disabled` option in the `/etc/selinux/config` results in a process in which the kernel boots with SELinux enabled and switches to disabled mode later in the boot process. This might cause memory leaks.

To work around this problem, disable SELinux by adding the `selinux=0` parameter to the kernel command line as described in the Changing SELinux modes at boot time section of the Using SELinux title if your scenario really requires to completely disable SELinux.

(JIRA:RHELPLAN-34199)

**sshd -T provides inaccurate information about Ciphers, MACs and KeX algorithms**

The output of the `sshd -T` command does not contain the system-wide crypto policy configuration or other options that could come from an environment file in `/etc/sysconfig/sshd` and that are applied as arguments on the `sshd` command. This occurs because the upstream OpenSSH project did not support the Include directive to support Red-Hat-provided cryptographic defaults in RHEL 8. Crypto policies are applied as command-line arguments to the `sshd` executable in the `sshd.service` unit during the service’s start by using an EnvironmentFile. To work around the problem, use the `source` command with the environment file and pass the crypto policy as an argument to the `sshd` command, as in `sshd -T $CRYPTO_POLICY`. For additional information, see Ciphers, MACs or KeX algorithms differ from `sshd -T` to what is provided by current crypto policy level. As a result, the output from `sshd -T` matches the currently configured crypto policy.

(BZ#2044354)

**OpenSSL in FIPS mode accepts only specific D-H parameters**

In FIPS mode, TLS clients that use OpenSSL return a bad dh value error and abort TLS connections to servers that use manually generated parameters. This is because OpenSSL, when configured to work in compliance with FIPS 140-2, works only with Diffie-Hellman parameters compliant to NIST SP 800-56A rev3 Appendix D (groups 14, 15, 16, 17, and 18 defined in RFC 3526 and with groups defined in RFC 7919). Also, servers that use OpenSSL ignore all other parameters and instead select known parameters of similar size. To work around this problem, use only the compliant groups.

(BZ#1810911)

**crypto-policies incorrectly allow Camellia ciphers**

The RHEL 8 system-wide cryptographic policies should disable Camellia ciphers in all policy levels, as stated in the product documentation. However, the Kerberos protocol enables the ciphers by default.

To work around the problem, apply the `NO-CAMELLIA` subpolicy:

```bash
# update-crypto-policies --set DEFAULT:NO-CAMELLIA
```

In the previous command, replace `DEFAULT` with the cryptographic level name if you have switched from `DEFAULT` previously.

As a result, Camellia ciphers are correctly disallowed across all applications that use system-wide crypto policies only when you disable them through the workaround.
Smart-card provisioning process through OpenSC pkcs15-init does not work properly

The file_caching option is enabled in the default OpenSC configuration, and the file caching functionality does not handle some commands from the pkcs15-init tool properly. Consequently, the smart-card provisioning process through OpenSC fails.

To work around the problem, add the following snippet to the /etc/opensc.conf file:

```plaintext
app pkcs15-init {
    framework pkcs15 {
        use_file_caching = false;
    }
}
```

The smart-card provisioning through pkcs15-init only works if you apply the previously described workaround.

Connections to servers with SHA-1 signatures do not work with GnuTLS

SHA-1 signatures in certificates are rejected by the GnuTLS secure communications library as insecure. Consequently, applications that use GnuTLS as a TLS backend cannot establish a TLS connection to peers that offer such certificates. This behavior is inconsistent with other system cryptographic libraries.

To work around this problem, upgrade the server to use certificates signed with SHA-256 or stronger hash, or switch to the LEGACY policy.

IKE over TCP connections do not work on custom TCP ports

The tcp-remoteport Libreswan configuration option does not work properly. Consequently, an IKE over TCP connection cannot be established when a scenario requires specifying a non-default TCP port.

Remediating service-related rules during kickstart installations might fail

During a kickstart installation, the OpenSCAP utility sometimes incorrectly shows that a service enable or disable state remediation is not needed. Consequently, OpenSCAP might set the services on the installed system to a non-compliant state. As a workaround, you can scan and remediate the system after the kickstart installation. This will fix the service-related issues.

Red Hat provides the CVE OVAL reports in compressed format

Red Hat provides CVE OVAL feeds in the bzip2-compressed format, and they are no longer available in the XML file format. The location of feeds for RHEL 8 has been updated accordingly to reflect this change. Because referencing compressed content is not standardized, third-party SCAP scanners can have problems with scanning rules that use the feed.

Certain sets of interdependent rules in SSG can fail
Remediation of SCAP Security Guide (SSG) rules in a benchmark can fail due to undefined ordering of rules and their dependencies. If two or more rules need to be executed in a particular order, for example, when one rule installs a component and another rule configures the same component, they can run in the wrong order and remediation reports an error. To work around this problem, run the remediation twice, and the second run fixes the dependent rules.

(BZ#1750755)

Server with GUI and Workstation installations are not possible with CIS Server profiles

The CIS Server Level 1 and Level 2 security profiles are not compatible with the Server with GUI and Workstation software selections. As a consequence, a RHEL 8 installation with the Server with GUI software selection and CIS Server profiles is not possible. An attempted installation using the CIS Server Level 1 or Level 2 profiles and either of these software selections will generate the error message:

```
package xorg-x11-server-common has been added to the list of excluded packages, but it can't be removed from the current software selection without breaking the installation.
```

If you need to align systems with the Server with GUI or Workstation software selections according to CIS benchmarks, use the CIS Workstation Level 1 or Level 2 profiles instead.

(BZ#1843932)

Kickstart uses org_fedora_oscap instead of com_redhat_oscap in RHEL 8

The Kickstart references the Open Security Content Automation Protocol (OSCAP) Anaconda add-on as org_fedora_oscap instead of com_redhat_oscap, which might cause confusion. This is necessary for backwards compatibility backward compatibility with Red Hat Enterprise Linux 7.

(BZ#1665082)

SSH timeout rules in STIG profiles configure incorrect options

An update of OpenSSH affected the rules in the following Defense Information Systems Agency Security Technical Implementation Guide (DISA STIG) profiles:

- DISA STIG for RHEL 8 (`xccdf_org.ssgproject.content_profile_stig`)
- DISA STIG with GUI for RHEL 8 (`xccdf_org.ssgproject.content_profile_stig_gui`)

In each of these profiles, the following two rules are affected:

Title: Set SSH Client Alive Count Max to zero
CCE Identifier: CCE-83405-1
Rule ID: xccdf_org.ssgproject.content_rule_sshd_set_keepalive_0
STIG ID: RHEL-08-010200

Title: Set SSH Idle Timeout Interval
CCE Identifier: CCE-80906-1
Rule ID: xccdf_org.ssgproject.content_rule_sshd_set_idle_timeout
STIG ID: RHEL-08-010201

When applied to SSH servers, each of these rules configures an option (ClientAliveCountMax and ClientAliveInterval) that no longer behaves as previously. As a consequence, OpenSSH no longer disconnects idle SSH users when it reaches the timeout configured by these rules. As a workaround, these rules have been temporarily removed from the DISA STIG for RHEL 8 and DISA STIG with GUI for RHEL 8 profiles until a solution is developed.
scap-workbench cannot scan remote systems from RHEL 8 hosts

Due to a bug in the kernel which blocks executed Qt subprocesses (BZ#2044587), sending of content files to the scanned system hangs and never completes. As a consequence, scanning of remote systems using the `scap-workbench` command from RHEL 8 hosts does not work. The scanning process hangs while content files are being sent to the scanned system, even before the scan begins. To work around this problem, when remotely scanning systems from RHEL 8 hosts, use the `dry-run` option to extract the equivalent `oscap-ssh` command and enter that command. As a consequence, you can scan the remote system with `oscap-ssh` to the same extent as with `scap-workbench`.

Certain `rsyslog` priority strings do not work correctly

Support for the GnuTLS priority string for `imtcp` that allows fine-grained control over encryption is not complete. Consequently, the following priority strings do not work properly in `rsyslog`:

```
```

To work around this problem, use only correctly working priority strings:

```
```

As a result, current configurations must be limited to the strings that work correctly.

Negative effects of the default logging setup on performance

The default logging environment setup might consume 4 GB of memory or even more and adjustments of rate-limit values are complex when `systemd-journald` is running with `rsyslog`.

See the Negative effects of the RHEL default logging setup on performance and their mitigations Knowledgebase article for more information.

NetworkManager does not support activating bond and team ports in a specific order

NetworkManager activates interfaces alphabetically by interface names. However, if an interface appears later during the boot, for example, because the kernel needs more time to discover it, NetworkManager activates this interface later. NetworkManager does not support setting a priority on bond and team ports. Consequently, the order in which NetworkManager activates ports of these devices is not always predictable. To work around this problem, write a dispatcher script.

For an example of such a script, see the corresponding comment in the ticket.

Systems with the `IPv6_rpfilter` option enabled experience low network throughput
Systems with the `IPv6_rpfilter` option enabled in the `firewalld.conf` file currently experience suboptimal performance and low network throughput in high traffic scenarios, such as 100-Gbps links. To work around the problem, disable the `IPv6_rpfilter` option. To do so, add the following line in the `/etc/firewalld/firewalld.conf` file.

```
IPv6_rpfilter=no
```

As a result, the system performs better, but also has reduced security.  
(BZ#1871860)

8.8. KERNEL

Using `net_prio` or `net_cls` controllers in v1 mode deactivates some controllers of the `cgroup-v2` hierarchy

In `cgroup-v2` environments, using either `net_prio` or `net_cls` controllers in v1 mode disables the hierarchical tracking of socket data. As a result, the `cgroup-v2` hierarchy for socket data tracking controllers is not active, and the `dmesg` command reports the following message:

```
cgroup: cgroup: disabling cgroup2 socket matching due to net_prio or net_cls activation
```

(BZ#2046396)

Reloading an identical crash extension may cause segmentation faults

When you load a copy of an already loaded crash extension file, it might trigger a segmentation fault. Currently, the crash utility detects if an original file has been loaded. Consequently, due to two identical files co-existing in the crash utility, a namespace collision occurs, which triggers the crash utility to cause a segmentation fault.

You can work around the problem by loading the crash extension file only once. As a result, segmentation faults no longer occur in the described scenario.  
(BZ#1906482)

vmcore capture fails after memory hot-plug or unplug operation

After performing the memory hot-plug or hot-unplug operation, the event comes after updating the device tree which contains memory layout information. Thereby the `makedumpfile` utility tries to access a non-existent physical address. The problem appears if all of the following conditions meet:

- A little-endian variant of IBM Power System runs RHEL 8.
- The `kdump` or `fadump` service is enabled on the system.

Consequently, the capture kernel fails to save `vmcore` if a kernel crash is triggered after the memory hot-plug or hot-unplug operation.

To work around this problem, restart the `kdump` service after hot-plug or hot-unplug:

```
# systemctl restart kdump.service
```

As a result, `vmcore` is successfully saved in the described scenario.  
(BZ#1793389)
Debug kernel fails to boot in crash capture environment on RHEL 8

Due to the memory-intensive nature of the debug kernel, a problem occurs when the debug kernel is in use and a kernel panic is triggered. As a consequence, the debug kernel is not able to boot as the capture kernel and a stack trace is generated instead. To work around this problem, increase the crash kernel memory as required. As a result, the debug kernel boots successfully in the crash capture environment.

(BZ#1659609)

Allocating crash kernel memory fails at boot time

On some Ampere Altra systems, allocating the crash kernel memory during boot fails when the 32-bit region is disabled in BIOS settings. Consequently, the `kdump` service fails to start. This is caused by memory fragmentation in the region below 4 GB with no fragment being large enough to contain the crash kernel memory.

To work around this problem, enable the 32-bit memory region in BIOS as follows:

1. Open the BIOS settings on your system.
2. Open the Chipset menu.
3. Under Memory Configuration, enable the Slave 32-bit option.

As a result, crash kernel memory allocation within the 32-bit region succeeds and the `kdump` service works as expected.

(BZ#1940674)

The kernel ACPI driver reports it has no access to a PCIe ECAM memory region

The Advanced Configuration and Power Interface (ACPI) table provided by firmware does not define a memory region on the PCI bus in the Current Resource Settings (_CRS) method for the PCI bus device. Consequently, the following warning message occurs during the system boot:

```
[ 2.817152] acpi PNP0A08:00: [Firmware Bug]: ECAM area [mem 0x30000000-0x31ffffff] not reserved in ACPI namespace
[ 2.827911] acpi PNP0A08:00: ECAM at [mem 0x30000000-0x31ffffff] for [bus 00-1f]
```

However, the kernel is still able to access the `0x30000000-0x31ffffff` memory region, and can assign that memory region to the PCI Enhanced Configuration Access Mechanism (ECAM) properly. You can verify that PCI ECAM works correctly by accessing the PCIe configuration space over the 256 byte offset with the following output:

```
03:00.0 Non-Volatile memory controller: Sandisk Corp WD Black 2018/PC SN720 NVMe SSD (prog-if 02 [NVM Express])
...
Capabilities: [900 v1] L1 PM Substates
   L1SubCap: PCI-PM_L1.2- PCI-PM_L1.1- ASPM_L1.2+ ASPM_L1.1- L1_PM_Substates+
   PortCommonModeRestoreTime=255us PortTPowerOnTime=10us
   L1SubCtl1: PCI-PM_L1.2- PCI-PM_L1.1- ASPM_L1.2- ASPM_L1.1-
      T_CommonMode=0us LTR1.2_Threshold=0ns
   L1SubCtl2: T_PwrOn=10us
```

As a result, you can ignore the warning message.
For more information about the problem, see the "Firmware Bug: ECAM area mem 0x30000000-0x31ffffff not reserved in ACPI namespace" appears during system boot solution.

(BZ#1868526)

The tuned-adm profile powersave command causes the system to become unresponsive

Executing the tuned-adm profile powersave command leads to an unresponsive state of the Penguin Valkyrie 2000 2-socket systems with the older Thunderx (CN88xx) processors. Consequently, reboot the system to resume working. To work around this problem, avoid using the powersave profile if your system matches the mentioned specifications.

(BZ#1609288)

The HP NMI watchdog does not always generate a crash dump

In certain cases, the hpwdt driver for the HP NMI watchdog is not able to claim a non-maskable interrupt (NMI) generated by the HPE watchdog timer because the NMI was instead consumed by the perfmon driver.

The missing NMI is initiated by one of two conditions:

1. The Generate NMI button on the Integrated Lights-Out (iLO) server management software. This button is triggered by a user.
2. The hpwdt watchdog. The expiration by default sends an NMI to the server.

Both sequences typically occur when the system is unresponsive. Under normal circumstances, the NMI handler for both these situations calls the kernel panic() function and if configured, the kdump service generates a vmcore file.

Because of the missing NMI, however, kernel panic() is not called and vmcore is not collected.

In the first case (1.), if the system was unresponsive, it remains so. To work around this scenario, use the virtual Power button to reset or power cycle the server.

In the second case (2.), the missing NMI is followed 9 seconds later by a reset from the Automated System Recovery (ASR).

The HPE Gen9 Server line experiences this problem in single-digit percentages. The Gen10 at an even smaller frequency.

(BZ#1602962)

Using irqpoll causes vmcore generation failure

Due to an existing problem with the nvme driver on the 64-bit ARM architecture that run on the Amazon Web Services (AWS) cloud platforms, causes vmcore generation failure when you provide the irqpoll kernel command line parameter to the first kernel. Consequently, no vmcore file is dumped in the /var/crash/ directory upon a kernel crash. To work around this problem:

1. Append irqpoll to KDUMP_COMMANDLINE_REMOVE in the /etc/sysconfig/kdump file.

```
KDUMP_COMMANDLINE_REMOVE="hugepages hugepagesz slub_debug quiet log_buf_len swiotlb"
```

2. Remove irqpoll from KDUMP_COMMANDLINE_APPEND in the /etc/sysconfig/kdump file.
KDUMP_COMMANDLINE_APPEND="irqpoll nr_cpus=1 reset_devices
cgroup_disable=memory udev.children-max=2 panic=10 swiotlb=noforce novmcoredd"

3. Restart the **kdump** service:

```
systemctl restart kdump
```

As a result, the first kernel boots correctly and the **vmcore** file is expected to be captured upon the kernel crash.

Note that the **kdump** service can use a significant amount of crash kernel memory to dump the **vmcore** file. Ensure that the capture kernel has sufficient memory available for the **kdump** service.

For related information on this Known Issue, see the **The irqpoll kernel command line parameter might cause vmcore generation failure** article.

*(BZ#1654962)*

**Connections fail when attaching a virtual function to virtual machine**

Pensando network cards that use the **ionic** device driver silently accept VLAN tag configuration requests and attempt configuring network connections while attaching network virtual functions (**VF**) to a virtual machine (**VM**). Such network connections fail as this feature is not yet supported by the card’s firmware.

*(BZ#1930576)*

**The OPEN MPI library may trigger run-time failures with default PML**

In OPEN Message Passing Interface (OPEN MPI) implementation 4.0.x series, Unified Communication X (UCX) is the default point-to-point communicator (PML). The later versions of OPEN MPI 4.0.x series deprecated **openib** Byte Transfer Layer (BTL).

However, OPEN MPI, when run over a **homogeneous** cluster (same hardware and software configuration), UCX still uses **openib** BTL for MPI one-sided operations. As a consequence, this may trigger execution errors. To work around this problem:

- Run the **mpirun** command using following parameters:

```
-mca btl openib -mca pml ucx -x UCX_NET_DEVICES=mlx5_ib0
```

where,

- The **-mca btl openib** parameter disables **openib** BTL
- The **-mca pml ucx** parameter configures OPEN MPI to use **ucx** PML.
- The **x UCX_NET_DEVICES=** parameter restricts UCX to use the specified devices

The OPEN MPI, when run over a **heterogeneous** cluster (different hardware and software configuration), it uses UCX as the default PML. As a consequence, this may cause the OPEN MPI jobs to run with erratic performance, unresponsive behavior, or crash failures. To work around this problem, set the UCX priority as:

- Run the **mpirun** command using following parameters:
As a result, the OPEN MPI library is able to choose an alternative available transport layer over UCX.

(BZ#1866402)

The Solarflare fails to create maximum number of virtual functions (VFs)

The Solarflare NICs fail to create a maximum number of VFs due to insufficient resources. You can check the maximum number of VFs that a PCIe device can create in the `/sys/bus/pci/devices/PCI_ID/sriov_totalvfs` file. To workaround this problem, you can either adjust the number of VFs or the VF MSI interrupt value to a lower value, either from Solarflare Boot Manager on startup, or using Solarflare `sfboot` utility. The default VF MSI interrupt value is 8.

- To adjust the VF MSI interrupt value using `sfboot`:

```
# sfboot vf-msix-limit=2
```

**NOTE**

Adjusting VF MSI interrupt value affects the VF performance.

For more information about parameters to be adjusted accordingly, see the Solarflare Server Adapter user guide.

(BZ#1971506)

8.9. FILE SYSTEMS AND STORAGE

Limitations of LVM writecache

The `writecache` LVM caching method has the following limitations, which are not present in the `cache` method:

- You cannot name a `writecache` logical volume when using `pvmove` commands.
- You cannot use logical volumes with `writecache` in combination with thin pools or VDO.

The following limitation also applies to the `cache` method:

- You cannot resize a logical volume while `cache` or `writecache` is attached to it.

(JIRA:RHELPLAN-27987, BZ#1798631, BZ#1808012)

XFS quota warnings are triggered too often

Using the quota timer results in quota warnings triggering too often, which causes soft quotas to be enforced faster than they should. To work around this problem, do not use soft quotas, which will prevent triggering warnings. As a result, the amount of warning messages will not enforce soft quota limit anymore, respecting the configured timeout.

(BZ#2059262)

LVM mirror devices that store a LUKS volume sometimes become unresponsive
Mirrored LVM devices with a segment type of mirror that store a LUKS volume might become unresponsive under certain conditions. The unresponsive devices reject all I/O operations.

To work around the issue, Red Hat recommends that you use LVM RAID 1 devices with a segment type of raid1 instead of mirror if you need to stack LUKS volumes on top of resilient software-defined storage.

The raid1 segment type is the default RAID configuration type and replaces mirror as the recommended solution.

To convert mirror devices to raid, see Converting a mirrored LVM device to a RAID1 device.

(BZ#1730502)

The /boot file system cannot be placed on LVM

You cannot place the /boot file system on an LVM logical volume. This limitation exists for the following reasons:

- On EFI systems, the EFI System Partition conventionally serves as the /boot file system. The uEFI standard requires a specific GPT partition type and a specific file system type for this partition.
- RHEL 8 uses the Boot Loader Specification (BLS) for system boot entries. This specification requires that the /boot file system is readable by the platform firmware. On EFI systems, the platform firmware can read only the /boot configuration defined by the uEFI standard.
- The support for LVM logical volumes in the GRUB 2 boot loader is incomplete. Red Hat does not plan to improve the support because the number of use cases for the feature is decreasing due to standards such as uEFI and BLS.

Red Hat does not plan to support /boot on LVM. Instead, Red Hat provides tools for managing system snapshots and rollback that do not need the /boot file system to be placed on an LVM logical volume.

(BZ#1496229)

LVM no longer allows creating volume groups with mixed block sizes

LVM utilities such as vgcreate or vgextend no longer allow you to create volume groups (VGs) where the physical volumes (PVs) have different logical block sizes. LVM has adopted this change because file systems fail to mount if you extend the underlying logical volume (LV) with a PV of a different block size.

To re-enable creating VGs with mixed block sizes, set the allow_mixed_block_sizes=1 option in the lvm.conf file.

(BZ#1768536)

Using Device mapper multipath with the NVMe/TCP driver causes system instability

DM multipath is not supported with the NVMe/TCP driver. Using it causes sleeping functions in the kernel to be called in an atomic context, which then results in system instability.

To workaround the problem, enable native NVMe multipath. Do not use DM multipath tools. For RHEL 8, add the option nvme_core.multipath=Y to the kernel command line.

(BZ#2022359)

The blk-availability systemd service deactivates complex device stacks
In systemd, the default block deactivation code does not always handle complex stacks of virtual block devices correctly. In some configurations, virtual devices might not be removed during the shutdown, which causes error messages to be logged. To work around this problem, deactivate complex block device stacks by executing the following command:

```bash
# systemctl enable --now blk-availability.service
```

As a result, complex virtual device stacks are correctly deactivated during shutdown and do not produce error messages.

(BZ#2011699)

8.10. DYNAMIC PROGRAMMING LANGUAGES, WEB AND DATABASE SERVERS

**getpwnam() might fail when called by a 32-bit application**

When a user of NIS uses a 32-bit application that calls the `getpwnam()` function, the call fails if the `nss_nis.i686` package is missing. To work around this problem, manually install the missing package by using the `yum install nss_nis.i686` command.

(BZ#1803161)

**MariaDB 10.5 does not warn about dropping a non-existent table when the OQGraph plug-in is enabled**

When the OQGraph storage engine plug-in is loaded to the MariaDB 10.5 server, MariaDB does not warn about dropping a non-existent table. In particular, when the user attempts to drop a non-existent table using the `DROP TABLE` or `DROP TABLE IF EXISTS` SQL commands, MariaDB neither returns an error message nor logs a warning.

Note that the OQGraph plug-in is provided by the `mariadb-oqgraph-engine` package, which is not installed by default.

(BZ#1944653)

**PAM plug-in version 1.0 does not work in MariaDB**

MariaDB 10.3 provides the Pluggable Authentication Modules (PAM) plug-in version 1.0. MariaDB 10.5 provides the plug-in versions 1.0 and 2.0, version 2.0 is the default.

The MariaDB PAM plug-in version 1.0 does not work in RHEL 8. To work around this problem, use the PAM plug-in version 2.0 provided by the `mariadb:10.5` module stream.

(BZ#1942330)

**Symbol conflicts between OpenLDAP libraries might cause crashes in httpd**

When both the `libldap` and `libldap_r` libraries provided by OpenLDAP are loaded and used within a single process, symbol conflicts between these libraries might occur. Consequently, Apache httpd child processes using the PHP `ldap` extension might terminate unexpectedly if the `mod_security` or `mod_auth_openidc` modules are also loaded by the `httpd` configuration.

Since the RHEL 8.3 update to the Apache Portable Runtime (APR) library, you can work around the problem by setting the `APR_DEEPBIND` environment variable, which enables the use of the `RTLD_DEEPBIND` dynamic linker option when loading `httpd` modules. When the `APR_DEEPBIND`
environment variable is enabled, crashes no longer occur in httpd configurations that load conflicting libraries.

(BZ#1819607)

8.11. IDENTITY MANAGEMENT

Windows Server 2008 R2 and earlier no longer supported

In RHEL 8.4 and later, Identity Management (IdM) does not support establishing trust to Active Directory with Active Directory domain controllers running Windows Server 2008 R2 or earlier versions. RHEL IdM now requires SMB encryption when establishing the trust relationship, which is only available with Windows Server 2012 or later.

(BZ#1971061)

Using the cert-fix utility with the --agent-uid pkidbuser option breaks Certificate System

Using the cert-fix utility with the --agent-uid pkidbuser option corrupts the LDAP configuration of Certificate System. As a consequence, Certificate System might become unstable and manual steps are required to recover the system.

(BZ#1729215)

The /var/log/lastlog sparse file on IdM hosts can cause performance problems

During the IdM installation, a range of 200,000 UIDs from a total of 10,000 possible ranges is randomly selected and assigned. Selecting a random range in this way significantly reduces the probability of conflicting IDs in case you decide to merge two separate IdM domains in the future.

However, having high UIDs can create problems with the /var/log/lastlog file. For example, if a user with the UID of 12800000008 logs in to an IdM client, the local /var/log/lastlog file size increases to almost 400 GB. Although the actual file is sparse and does not use all that space, certain applications are not designed to identify sparse files by default and may require a specific option to handle them. For example, if the setup is complex and a backup and copy application does not handle sparse files correctly, the file is copied as if its size was 400 GB. This behavior can cause performance problems. To work around this problem:

- In case of a standard package, refer to its documentation to identify the option that handles sparse files.
- In case of a custom application, ensure that it is able to manage sparse files such as /var/log/lastlog correctly.

(JIRA:RHELPLAN-59111)

FIPS mode does not support using a shared secret to establish a cross-forest trust

Establishing a cross-forest trust using a shared secret fails in FIPS mode because NTLMSSP authentication is not FIPS-compliant. To work around this problem, authenticate with an Active Directory (AD) administrative account when establishing a trust between an IdM domain with FIPS mode enabled and an AD domain.

(BZ#1924707)

FreeRADIUS server fails to run in FIPS mode
By default, in FIPS mode, OpenSSL disables the use of the MD5 digest algorithm. As the RADIUS protocol requires MD5 to encrypt a secret between the RADIUS client and the RADIUS server, this causes the FreeRADIUS server to fail in FIPS mode.

To work around this problem, follow these steps:

**Procedure**

1. Create the environment variable, `RADIUS_MD5_FIPS_OVERRIDE` for the `radiusd` service:

```
systemctl edit radiusd

[Service]
Environment=RADIUS_MD5_FIPS_OVERRIDE=1
```

2. To apply the change, reload the `systemd` configuration and start the `radiusd` service:

```
# systemctl daemon-reload
# systemctl start radiusd
```

3. To run FreeRADIUS in debug mode:

```
# RADIUS_MD5_FIPS_OVERRIDE=1 radiusd -X
```

Note that though FreeRADIUS can run in FIPS mode, this does not mean that it is FIPS compliant as it uses weak ciphers and functions when in FIPS mode.

For more information on configuring FreeRADIUS authentication in FIPS mode, see [How to configure FreeRADIUS authentication in FIPS mode](#).

(BZ#1958979)

**Actions required when running Samba as a print server and updating from RHEL 8.4 and earlier**

With this update, the `samba` package no longer creates the `/var/spool/samba/` directory. If you use Samba as a print server and use `/var/spool/samba/` in the `[printers]` share to spool print jobs, SELinux prevents Samba users from creating files in this directory. Consequently, print jobs fail and the `auditd` service logs a `denied` message in `/var/log/audit/audit.log`. To avoid this problem after updating your system from 8.4 and earlier:

1. Search the `[printers]` share in the `/etc/samba/smb.conf` file.

2. If the share definition contains `path = /var/spool/samba/`, update the setting and set the `path` parameter to `/var/tmp/`.

3. Restart the `smbd` service:

```
# systemctl restart smbd
```

If you newly installed Samba on RHEL 8.5 or later, no action is required. The default `/etc/samba/smb.conf` file provided by the `samba-common` package in this case already uses the `/var/tmp/` directory to spool print jobs.

(BZ#2009213)
Downgrading authselect after the rebase to version 1.2.2 breaks system authentication

The authselect package has been rebased to the latest upstream version 1.2.2. Downgrading authselect is not supported and breaks system authentication for all users, including root.

If you downgraded the authselect package to 1.2.1 or earlier, perform the following steps to work around this problem:

1. At the GRUB boot screen, select Red Hat Enterprise Linux with the version of the kernel that you want to boot and press e to edit the entry.

2. Type single as a separate word at the end of the line that starts with linux and press Ctrl+X to start the boot process.

3. Upon booting in single-user mode, enter the root password.

4. Restore authselect configuration using the following command:

```
# authselect select sssd --force
```

(BZ#1892761)

The default keyword for enabled ciphers in the NSS does not work in conjunction with other ciphers

In Directory Server you can use the default keyword to refer to the default ciphers enabled in the network security services (NSS). However, if you want to enable the default ciphers and additional ones using the command line or web console, Directory Server fails to resolve the default keyword. As a consequence, the server enables only the additionally specified ciphers and logs the following error:

```
Security Initialization - SSL alert: Failed to set SSL cipher preference information: invalid ciphers <default,+__cipher_name__>: format is +cipher1,-cipher2... (Netscape Portable Runtime error 0 - no error)
```

As a workaround, specify all ciphers that are enabled by default in NSS including the ones you want to additionally enable.

(BZ#1817505)

8.12. DESKTOP

Disabling flatpak repositories from Software Repositories is not possible

Currently, it is not possible to disable or remove flatpak repositories in the Software Repositories tool in the GNOME Software utility.

(BZ#1668760)

Generation 2 RHEL 8 virtual machines sometimes fail to boot on Hyper-V Server 2016 hosts

When using RHEL 8 as the guest operating system on a virtual machine (VM) running on a Microsoft Hyper-V Server 2016 host, the VM in some cases fails to boot and returns to the GRUB boot menu. In addition, the following error is logged in the Hyper-V event log:

```
The guest operating system reported that it failed with the following error code: 0x1E
```
This error occurs due to a UEFI firmware bug on the Hyper-V host. To work around this problem, use Hyper-V Server 2019 or later as the host.

(BZ#1583445)

Drag-and-drop does not work between desktop and applications

Due to a bug in the gnome-shell-extensions package, the drag-and-drop functionality does not currently work between desktop and applications. Support for this feature will be added back in a future release.

(BZ#1717947)

8.13. GRAPHICS INFRASTRUCTURES

Matrox GPU with a VGA display shows no output

Your display might show no graphical output if you use the following system configuration:

- A GPU in the Matrox MGA G200 family
- A display connected over the VGA controller
- UEFI switched to legacy mode

As a consequence, you cannot use or install RHEL on this configuration.

To work around the problem, use the following procedure:

1. Boot the system to the boot loader menu.
2. Add the nomodeset option to the kernel command line.

As a result, RHEL boots and shows graphical output as expected, but the maximum resolution is limited.

(BZ#1953926)

radeon fails to reset hardware correctly

The radeon kernel driver currently does not reset hardware in the kexec context correctly. Instead, radeon falls over, which causes the rest of the kdump service to fail.

To work around this problem, disable radeon in kdump by adding the following line to the /etc/kdump.conf file:

```
dracut_args --omit-drivers "radeon"
force_rebuild 1
```

Restart the machine and kdump. After starting kdump, the force_rebuild 1 line may be removed from the configuration file.

Note that in this scenario, no graphics will be available during kdump, but kdump will work successfully.

(BZ#1694705)

Multiple HDR displays on a single MST topology may not power on
On systems using NVIDIA Turing GPUs with the **nouveau** driver, using a **DisplayPort** hub (such as a laptop dock) with multiple monitors which support HDR plugged into it may result in failure to turn on. This is due to the system erroneously thinking there is not enough bandwidth on the hub to support all of the displays.

(BZ#1812577)

**GUI in ESXi might crash due to low video memory**

The graphical user interface (GUI) on RHEL virtual machines (VMs) in the VMware ESXi 7.0.1 hypervisor with vCenter Server 7.0.1 requires a certain amount of video memory. If you connect multiple consoles or high-resolution monitors to the VM, the GUI requires at least 16 MB of video memory. If you start the GUI with less video memory, the GUI might terminate unexpectedly.

To work around the problem, configure the hypervisor to assign at least 16 MB of video memory to the VM. As a result, the GUI on the VM no longer crashes.

(BZ#1910358)

**VNC Viewer displays wrong colors with the 16-bit color depth on IBM Z**

The VNC Viewer application displays wrong colors when you connect to a VNC session on an IBM Z server with the 16-bit color depth.

To work around the problem, set the 24-bit color depth on the VNC server. With the **Xvnc** server, replace the `-depth 16` option with `-depth 24` in the **Xvnc** configuration.

As a result, VNC clients display the correct colors but use more network bandwidth with the server.

(BZ#1886147)

**Unable to run graphical applications using sudo command**

When trying to run graphical applications as a user with elevated privileges, the application fails to open with an error message. The failure happens because **Xwayland** is restricted by the **Xauthority** file to use regular user credentials for authentication.

To work around this problem, use the `sudo -E` command to run graphical applications as a **root** user.

(BZ#1673073)

**Hardware acceleration is not supported on ARM**

Built-in graphics drivers do not support hardware acceleration or the Vulkan API on the 64-bit ARM architecture.

To enable hardware acceleration or Vulkan on ARM, install the proprietary Nvidia driver.

(JIRA:RHELPLAN-57914)

**8.14. THE WEB CONSOLE**

**Removing USB host devices using the web console does not work as expected**

When you attach a USB device to a virtual machine (VM), the device number and bus number of the USB device might change after they are passed to the VM. As a consequence, using the web console to remove such devices fails due to the incorrect correlation of the device and bus numbers. To
workaround this problem, remove the `<hostdev>` part of the USB device, from the VM’s XML configuration.

(JIRA:RHELPLAN-109067)

**Attaching multiple host devices using the web console does not work**

When you select multiple devices to attach to a virtual machine (VM) using the web console, only a single device is attached and the rest are ignored. To work around this problem, attach only one device at a time.

(JIRA:RHELPLAN-115603)

### 8.15. RED HAT ENTERPRISE LINUX SYSTEM ROLES

**Unable to manage localhost by using the localhost hostname in the playbook or inventory**

With the inclusion of the `ansible-core 2.12` package in RHEL, if you are running Ansible on the same host you manage your nodes, you cannot do it by using the `localhost` hostname in your playbook or inventory. This happens because `ansible-core 2.12` uses the `python38` module, and many of the libraries are missing, for example, `blivet` for the `storage` role, `gobject` for the `network` role. To workaround this problem, if you are already using the `localhost` hostname in your playbook or inventory, you can add a connection, by using `ansible_connection=local`, or by creating an inventory file that lists `localhost` with the `ansible_connection=local` option. With that, you are able to manage resources on `localhost`. For more details, see the article [RHEL System Roles playbooks fail when run on localhost](https://access.redhat.com/documentation/en-us/enterprise_linux/8/html-single/management_guide/ch-apiconfig-management-system-roles)

(BZ#2041997)

### 8.16. VIRTUALIZATION

**Attaching LUN devices to virtual machines using virtio-blk does not work**

The q35 machine type does not support transitional virtio 1.0 devices, and RHEL 8 therefore lacks support for features that were deprecated in virtio 1.0. In particular, it is not possible on a RHEL 8 host to send SCSI commands from virtio-blk devices. As a consequence, attaching a physical disk as a LUN device to a virtual machine fails when using the virtio-blk controller.

Note that physical disks can still be passed through to the guest operating system, but they should be configured with the `device='disk'` option rather than `device='lun'`.

(BZ#1777138)

**Virtual machines with iommu_platform=on fail to start on IBM POWER**

RHEL 8 currently does not support the `iommu_platform=on` parameter for virtual machines (VMs) on IBM POWER system. As a consequence, starting a VM with this parameter on IBM POWER hardware results in the VM becoming unresponsive during the boot process.

(BZ#1910848)

**IBM POWER hosts may crash when using the ibmvfc driver**

When running RHEL 8 as a KVM virtualization host on a PowerVM logical partition (LPAR), a variety of errors may currently occur due problems with the `ibmvfc` driver. As a consequence, the host's kernel may panic under certain circumstances, such as:

- Using the Live Partition Mobility (LPM) feature
• Resetting a host adapter

• Using SCSI error handling (SCSI EH) functions

(BZ#1961722)

**Using perf kvm record on IBM POWER Systems can cause the VM to crash**

When using a RHEL 8 host on the little-endian variant of IBM POWER hardware, using the `perf kvm record` command to collect trace event samples for a KVM virtual machine (VM) in some cases results in the VM becoming unresponsive. This situation occurs when:

- The `perf` utility is used by an unprivileged user, and the `-p` option is used to identify the VM - for example `perf kvm record -e trace_cycles -p 12345`.
- The VM was started using the `virsh` shell.

To work around this problem, use the `perf kvm` utility with the `-i` option to monitor VMs that were created using the `virsh` shell. For example:

```
# perf kvm record -e trace_imc/trace_cycles/ -p <guest pid> -i
```

Note that when using the `-i` option, child tasks do not inherit counters, and threads will therefore not be monitored.

(BZ#1924016)

**Windows Server 2016 virtual machines with Hyper-V enabled fail to boot when using certain CPU models**

Currently, it is not possible to boot a virtual machine (VM) that uses Windows Server 2016 as the guest operating system, has the Hyper-V role enabled, and uses one of the following CPU models:

- EPYC-IBPB
- EPYC

To work around this problem, use the EPYC-v3 CPU model, or manually enable the `xsaves` CPU flag for the VM.

(BZ#1942888)

**Migrating a POWER9 guest from a RHEL 7-ALT host to RHEL 8 fails**

Currently, migrating a POWER9 virtual machine from a RHEL 7-ALT host system to RHEL 8 becomes unresponsive with a Migration status: active status.

To work around this problem, disable Transparent Huge Pages (THP) on the RHEL 7-ALT host, which enables the migration to complete successfully.

(BZ#1741436)

**Deleting a forward interface from a macvtap virtual network resets all connection counts of this network**

Currently, deleting a forward interface from a `macvtap` virtual network with multiple forward interfaces also resets the connection status of the other forward interfaces of the network. As a consequence, the connection information in the live network XML is incorrect. Note, however, that this does not affect the...
functionality of the virtual network. To work around the issue, restart the `libvirtd` service on your host.

(BZ#1332758)

**Virtual machines with SLOF fail to boot in netcat interfaces**

When using a netcat (`nc`) interface to access the console of a virtual machine (VM) that is currently waiting at the Slimline Open Firmware (SLOF) prompt, the user input is ignored and VM stays unresponsive. To work around this problem, use the `nc -C` option when connecting to the VM, or use a telnet interface instead.

(BZ#1974622)

**Attaching mediated devices to virtual machines in `virt-manager` in some cases fails**

The `virt-manager` application is currently able to detect mediated devices, but cannot recognize whether the device is active. As a consequence, attempting to attach an inactive mediated device to a running virtual machine (VM) using `virt-manager` fails. Similarly, attempting to create a new VM that uses an inactive mediated device fails with a `device not found` error.

To work around this issue, use the `virsh nodedev-start` or `mdevctl start` commands to activate the mediated device before using it in `virt-manager`.

(BZ#2026985)

**RHEL 9 virtual machines fail to boot in POWER8 compatibility mode**

Currently, booting a virtual machine (VM) that runs RHEL 9 as its guest operating system fails if the VM also uses CPU configuration similar to the following:

```
<cpu mode="host-model">
  <model>power8</model>
</cpu>
```

To work around this problem, do not use POWER8 compatibility mode in RHEL 9 VMs.

In addition, note that running RHEL 9 VMs is not possible on POWER8 hosts.

(BZ#2035158)

**Virtual machines sometimes fail to start when using many virtio-blk disks**

Adding a large number of virtio-blk devices to a virtual machine (VM) may exhaust the number of interrupt vectors available in the platform. If this occurs, the VM’s guest OS fails to boot, and displays a `dracut-initqueue[392]: Warning: Could not boot` error.

(BZ#1719687)

**SMT CPU topology is not detected by VMs when using host passthrough mode on AMD EPYC**

When a virtual machine (VM) boots with the CPU host passthrough mode on an AMD EPYC host, the `TOPOEXT` CPU feature flag is not present. Consequently, the VM is not able to detect a virtual CPU topology with multiple threads per core. To work around this problem, boot the VM with the EPYC CPU model instead of host passthrough.

(BZ#1740002)
8.17. RHEL IN CLOUD ENVIRONMENTS

SR-IOV performs suboptimally in ARM 64 RHEL 8 virtual machines on Azure

Currently, SR-IOV networking devices have significantly lower throughput and higher latency than expected in ARM 64 RHEL 8 virtual machines (VMs) running on a Microsoft Azure platform. (BZ#2068429)

Setting static IP in a RHEL 8 virtual machine on a VMware host does not work

Currently, when using RHEL 8 as a guest operating system of a virtual machine (VM) on a VMware host, the DatasourceOVF function does not work correctly. As a consequence, if you use the cloud-init utility to set the VM's network to static IP and then reboot the VM, the VM's network will be changed to DHCP. (BZ#1750862)

kdump sometimes does not start on Azure and Hyper-V

On RHEL 8 guest operating systems hosted on the Microsoft Azure or Hyper-V hypervisors, starting the kdump kernel in some cases fails when post-exec notifiers are enabled.

To work around this problem, disable crash kexec post notifiers:

```
# echo N > /sys/module/kernel/parameters/crash_kexec_post_notifiers
```
(BZ#1865745)

The SCSI host address sometimes changes when booting a Hyper-V VM with multiple guest disks

Currently, when booting a RHEL 8 virtual machine (VM) on the Hyper-V hypervisor, the host portion of the Host, Bus, Target, Lun (HBTL) SCSI address in some cases changes. As a consequence, automated tasks set up with the HBTL SCSI identification or device node in the VM do not work consistently. This occurs if the VM has more than one disk or if the disks have different sizes.

To work around the problem, modify your kickstart files, using one of the following methods:

**Method 1: Use persistent identifiers for SCSI devices.**

You can use for example the following powershell script to determine the specific device identifiers:

```
# Output what the /dev/disk/by-id/<value> for the specified hyper-v virtual disk.
# Takes a single parameter which is the virtual disk file.
# Note: kickstart syntax works with and without the /dev/ prefix.
param (
  [Parameter(Mandatory=$true)][string]$virtualdisk
)

$what = Get-VHD -Path $virtualdisk
$part = $what.DiskIdentifier.ToLower().split('-')

$p = $part[0]
$p = $part[1]
```
\[
\$s1 = \$p[2] + \$p[3] + \$p[0] + \$p[1]
\]

You can use this script on the hyper-v host, for example as follows:

```
PS C:\Users\Public\Documents\Hyper-V\Virtual hard disks> .\by-id.ps1 .\Testing_8\disk_3_8.vhdx
/dev/disk/by-id/wwn-0x60022480e00bc367d7fd902e8bf0d3b4
PS C:\Users\Public\Documents\Hyper-V\Virtual hard disks> .\by-id.ps1 .\Testing_8\disk_3_9.vhdx
/dev/disk/by-id/wwn-0x600224807270e09717645b1890f8a9a2
```

Afterwards, the disk values can be used in the kickstart file, for example as follows:

```
part / --fstype=xfs --grow --asprimary --size=8192 --ondisk=/dev/disk/by-id/wwn-0x600224807270e09717645b1890f8a9a2
part /home --fstype="xfs" --grow --ondisk=/dev/disk/by-id/wwn-0x60022480e00bc367d7fd902e8bf0d3b4
```

As these values are specific for each virtual disk, the configuration needs to be done for each VM instance. It may, therefore, be useful to use the `%include` syntax to place the disk information into a separate file.

**Method 2: Set up device selection by size.**

A kickstart file that configures disk selection based on size must include lines similar to the following:

```
... # Disk partitioning information is supplied in a file to kick start
%include /tmp/disks
...

# Partition information is created during install using the %pre section
%pre --interpreter /bin/bash --log /tmp/ks_pre.log

# Dump whole SCSI/IDE disks out sorted from smallest to largest outputting
# just the name
disks=(`lsblk -n -o NAME -l -b -x SIZE -d -I 8,3`) || exit 1

# We are assuming we have 3 disks which will be used
# and we will create some variables to represent
d0=${disks[0]}
d1=${disks[1]}
d2=${disks[2]}

echo "part /home --fstype="xfs" --ondisk=$d2 --grow" >> /tmp/disks
echo "part swap --fstype="swap" --ondisk=$d0 --size=4096" >> /tmp/disks
echo "part / --fstype="xfs" --ondisk=$d1 --grow" >> /tmp/disks
echo "part /boot --fstype="xfs" --ondisk=$d1 --size=1024" >> /tmp/disks

%end
```

(BZ#1906870)
Starting a RHEL 8 virtual machine on AWS using `cloud-init` takes longer than expected

Currently, initializing an EC2 instance of RHEL 8 using the `cloud-init` service on Amazon Web Services (AWS) takes an excessive amount of time. To avoid this problem, remove the `/etc/resolv.conf` file from the image you are using for VM creation before uploading the image to AWS.

(BZ#1862930)

8.18. SUPPORTABILITY

The `getattachment` command fails to download multiple attachments

The `getattachment` command is able to download only a single attachment, but fails to download multiple attachments.

As a workaround, you can download multiple attachments one by one by passing the case number and UUID for each attachment in the `getattachment` command.

(BZ#2064575)

`redhat-support-tool` does not work with the FUTURE crypto policy

Because a cryptographic key used by a certificate on the Customer Portal API does not meet the requirements by the FUTURE system-wide cryptographic policy, the `redhat-support-tool` utility does not work with this policy level at the moment.

To work around this problem, use the DEFAULT crypto policy while connecting to the Customer Portal API.

(BZ#1802026)

Timeout when running `sos report` on IBM Power Systems, Little Endian

When running the `sos report` command on IBM Power Systems, Little Endian with hundreds or thousands of CPUs, the processor plugin reaches its default timeout of 300 seconds when collecting huge content of the `/sys/devices/system/cpu` directory. As a workaround, increase the plugin’s timeout accordingly:

- For one-time setting, run:

  ```bash
  # sos report -k processor.timeout=1800
  ```

- For a permanent change, edit the `[plugin_options]` section of the `/etc/sos/sos.conf` file:

  ```conf
  [plugin_options]
  # Specify any plugin options and their values here. These options take the form
  # plugin_name.option_name = value
  #rpm.rpmva = off
  processor.timeout = 1800
  ```

  The example value is set to 1800. The particular timeout value highly depends on a specific system. To set the plugin’s timeout appropriately, you can first estimate the time needed to collect the one plugin with no timeout by running the following command:

  ```bash
  # time sos report -o processor -k processor.timeout=0 --batch --build
  ```
8.19. CONTAINERS

Running systemd within an older container image does not work

Running systemd within an older container image, for example, \texttt{centos:7}, does not work:

```
$ podman run --rm -ti centos:7 /usr/lib/systemd/systemd
```

Storing signatures

Failed to mount cgroup at /sys/fs/cgroup/systemd: Operation not permitted

[!!!!!!] Failed to mount API filesystems, freezing.

To work around this problem, use the following commands:

```
# mkdir /sys/fs/cgroup/systemd
# mount none -t cgroup -o none,name=systemd /sys/fs/cgroup/systemd
# podman run --runtime /usr/bin/crun --annotation=run.oci.systemd.force_cgroup_v1=./sys/fs/cgroup -
-rm -ti centos:7 /usr/lib/systemd/systemd
```

(JIRA:RHELPLAN-96940)

Container images signed with a Beta GPG key can not be pulled

Currently, when you try to pull RHEL Beta container images, \texttt{podman} exits with the error message: \texttt{Error: Source image rejected: None of the signatures were accepted}. The images fail to be pulled due to current builds being configured to not trust the RHEL Beta GPG keys by default.

As a workaround, ensure that the Red Hat Beta GPG key is stored on your local system and update the existing trust scope with the \texttt{podman image trust set} command for the appropriate beta namespace.

If you do not have the Beta GPG key stored locally, you can pull it by running the following command:

```
```

To add the Beta GPG key as trusted to your namespace, use one of the following commands:

```
$ sudo podman image trust set -f /etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-beta registry.access.redhat.com/namespace
```

and

```
$ sudo podman image trust set -f /etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-beta registry.redhat.io/namespace
```

Replace \texttt{namespace} with \texttt{ubi9-beta} or \texttt{rhel9-beta}.

(BZ#2020301)
9.1. RED HAT ENTERPRISE LINUX 8 INTERNATIONAL LANGUAGES

Red Hat Enterprise Linux 8 supports the installation of multiple languages and the changing of languages based on your requirements.

- European Languages - English, German, Spanish, French, Italian, Portuguese, and Russian.

The following table lists the fonts and input methods provided for various major languages.

<table>
<thead>
<tr>
<th>Language</th>
<th>Default Font (Font Package)</th>
<th>Input Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>English</td>
<td>dejavu-sans-fonts</td>
<td></td>

</tbody>
</table>

9.2. NOTABLE CHANGES TO INTERNATIONALIZATION IN RHEL 8

RHEL 8 introduces the following changes to internationalization compared to RHEL 7:

- Support for the **Unicode 11** computing industry standard has been added.
- Internationalization is distributed in multiple packages, which allows for smaller footprint installations. For more information, see [Using langpacks](#).
• A number of **glibc** locales have been synchronized with Unicode Common Locale Data Repository (CLDR).
Bugzilla and JIRA IDs are listed in this document for reference. Bugzilla bugs that are publicly accessible include a link to the ticket.
